This 'new' rural sociology – its critical perspective on corporate agriculture and its ties to the Land-Grant System – has been highly influential in the past, and it arguably also has contributed to rural sociology's marginalization within the university (as measured by the withdrawal of faculty lines and resources). The work of rural sociologists has sometimes been viewed as critical rather than constructive, as ideological rather than empirical. Of course, any 'new sociology' inevitability becomes 'old sociology,' and that is arguably the case with the new rural sociology. Recent changes in the theoretical, substantive, and organizational content of rural sociology arguably reflect the march of neoliberalism, the waning of Marxist and other critical perspectives in sociology, and the usual demographic turnover of university faculty.

Rural sociology today cannot be reduced to sociology of agriculture (located within the RSS) or even be viewed as a "heuristic device with which to begin reconstructing rural sociology" (Newby, 1983: p. 78). A new rural sociology for the

twenty-first century is perhaps best represented by a new synthesis of research and training between rural sociology and mainstream sociology. This should be viewed constructively as symmetrical rather than asymmetrical process of disciplinary, substantive, and intellectual influence, where rural sociology is not lost to sociology or otherwise extinguished intellectually. It is represented by not only a new organizational or administrative synthesis (described previously), but also the new realities of societal and global change and spatial interconnections. This can be observed by innovative new research – both by urban-oriented and rural-oriented sociologists – at the rural–urban interface. Rural and urban issues are increasingly viewed as flipsides of the same coin. The 'new' rural America is marked by growing spatial interdependence – a blurring of traditional rural–urban spatial and symbolic boundaries (Lichter and Brown, 2011).

Rural-related theory and research arguably has become increasingly integrated with urban and global perspectives, and vice versa. Indeed, a new rural sociology is also evident in its global spread, due in part to the missionary zeal of US rural sociologists – both today and in the past – who have sowed the intellectual and organizational seeds in a large number of developed and developing countries (Buttel, 2001). Today's sociology of agriculture, for example, has clear implications for labor mobility, hunger and obesity, poverty and spatial inequality, power and cooperation, urbanization and development, social movements and change, and many other substantive areas that almost always link spatial and social processes (e.g., commuting, leisure, cultural change, and media) to the broader sociological enterprise. Simple binary views of urban and rural represent conceptual and empirical roadblocks to understanding. In fact, the rural–urban interface is increasingly a zone of interdependence and social, economic, and political interaction; they arguably should be treated as such in sociological research and training (see Lichter and Brown, 2011). The new rural sociology is a place for disciplinary and substantive growth and innovation.

Abstract

Using its custom-made version of Marxism as a road map for the transformation of economy and society, the Bolshevik state acknowledged a role of culture. The early 1920s saw the unbridled creativity of futuristic projects in many domains of high culture. The next decade saw a decisive turn of the Soviet culture toward conservative ideas, with mass violence becoming the routine mechanism of political control. Paradoxically, oppression made culture politically relevant and power culturally productive. The Gulag became the central institution of Soviet culture, and mourning for its victims defined its later developments till the collapse of 1991.

Studies of Soviet culture (1922–91) – possibly, the most ideologically driven culture in modern history – were traditionally polarized by the ideological beliefs of its historians. Now that many of these controversies have passed away along with the Soviet Union, a new post-Soviet view of Soviet culture focuses on its symbolic center and the source of its unique energy: violence. Turning the experience of Stalinism and its crucial manifestation, the gulag system, into the central subject of Soviet cultural studies, this essay looks at the futuristic origins of Soviet culture, its culmination in the state terror of Stalinism, pubic mourning for its victims, and the final decay.

Origins

Collapse of the Russian Empire in the course of World War I opened up the space of Northern Eurasia for utopian ideas and radical practices. One of many competing Russian versions of Marxism, Bolshevism, emphasized the violent break with the past, which in its view could not be achieved by democratic methods. More than other varieties of Marxism, Bolshevism was preoccupied with the state, which it perceived as the agent of radical change while objectifying other spheres – private business, civil society, personal life – as the targets of the state and its transformative efforts. Bolshevism proclaimed the internationalist nature of the new state, which would pursue the global revolution rather than any national interest. Bolshevism saw its base in the union between proletariat and intellectuals, which was supposed to overcome the resistance of the old order. Finally, Bolshevism promoted collectivist values, which would develop the traditions of the organized proletariat rather than of the peasant commune and therefore, cement the institutes of the state rather than undermine them (Stites, 1989; Malia, 1994; Kharkhordin, 1999). Led by Leon Trotsky, the first generation of Bolshevik leaders (many of them former émigrés with years of cosmopolitan experience) understood the revolution in Russia as the first stage of the forthcoming 'world revolution,' which they imagined as a combination of class warfare with decolonization of global empires. In the devastated Europe, this militant utopianism gained a broad acclaim. When World War I ended, Bolshevism was internationally perceived as a menace to the old order. Records of the Paris Peace Conference (1919) document fears of the French, British, and even American statesmen that Bolshevism would spread from the East to the West of Europe, presenting a major alternative to the liberal, anti-imperial but pro-capitalist worldview of Woodrow Wilson's era.

Using 'the science of Marxism' as a road map for the transformation of economy and society, the Bolshevik state inadvertently acknowledged a major role of culture in this endeavor. The issue was not trivial: the Marxist political economy attributed to culture – a part of the 'superstructure' rather than of the 'basis' of social production – a secondary role. However, the radical transformational measures, which the early Soviet leadership implemented in education, labor control, family legislation, hygiene, social work, and other sectors of 'superstructure,' needed a theoretical justification. Trotsky and other leaders sponsored debates about the role of culture in the societal transformation, usually arriving at formulations of 'partial autonomy' of culture in social change. The early 1920s saw the unbridled creativity of futuristic projects in many domains of high culture – architecture, music, theater, visual arts, etc. Despite the brutality of Russia's Civil War, it was still an era of social optimism, which connected cultural innovation with the proclaimed purposes of the Soviet government. Created in 1922, the Soviet Union of four 'socialist republics' embodied the internationalist ideas of early Bolshevism. But in the mid-1920s, power slipped into the hands of Joseph Stalin and the second generation of Bolshevik leaders, who centralized political decisions and economic planning in Moscow, proclaimed the end of the 'world revolution,' and launched some of the most violent operations of the Soviet period, such as 'collectivization' of 1928. The beginning of the 1930s saw a decisive turn of the official Soviet culture toward conservative ideas in a broad range of human and social issues, from neoclassical trends in architecture and urbanism to 'pedological' experiments with testing in high schools, to the attempts at enforcing the 'new Soviet moral' in sex, family, and procreation, to confronting Soviet artists, writers, and musicians with the mandatory, ideologically charged style of 'Socialist Realism.' Gradually and without much reflection, culture was promoted into the rank of the highest value of the state and supervised personally by the

supreme leader, Stalin. Undermining the operative value of traditional values such as salvation, reason, or profit, Stalinism supplanted them by a broad, undifferentiated concept of culture. Now the Soviet state understood 'culture' as a controllable and controlled, inherently resistant but eventually complicit, system of symbols and institutions that promote the major goals of 'socialism.' On an individual level, Soviet culture defined its behavioral manifestation, 'culturedness,' which operated as a measure of personal appropriation of the officially approved culture and a skill of manifesting this culture in everyday life (Volkov, 2000). The ideal of 'culturedness' provided the agents of the state with a coherent, unilinear dimension of social control, which underlined various practices of discipline, assessment, and promotion. This period saw a proliferation of various methods, sometimes pioneering and sometimes imported from the West, which aimed at transforming everyday life by means of high culture: culinary books, methods of training in birth-giving, nursing, swaddling and other aspects of parenting, and mock trials that focused on sexual and marital life of the members of the 'working collective.'

Due to a paradoxical mechanism that Michel Foucault helps to elucidate in his "repressive hypothesis" (Rothberg, 2009), oppression made culture politically relevant and power culturally productive. Like its predecessor, the Russian empire, the Soviet authoritarian regime ambivalently perceived 'culture' as its favorite instrument but also an unknown threat – a weapon of resistance, a source of plurality and violation of the rules, and even a foreshadowing of the revolution. Culture became a screen on which the endangered society saw itself – a unique organ of self-awareness, critical feedback, mourning, and warning (Etkind, 2011).

Nationalities Question

Created as an open, voluntary coalition of formally independent states, the Soviet Union underwent a relentless centralization in political, economic, and military matters. But its leadership tolerated and even promoted a variety of cultural practices in its colonial domains, which spanned from Ukraine to the Caucasus to Central Asia to the Pacific coast to the enormous Arctic region. Trying to find the usable distinction between the cultural and the political, Stalinism endorsed a limited extent of cultural autonomy of the officially recognized 'republics.' Dozens of other peoples of the Soviet Union, who happened to dwell within the Russian or other 'socialist republics,' were deprived of their group rights. Some scholars see in these cultural policies an analog of 'affirmative action' toward republic-making ethnicities (Martin, 2001), but this analogy is limited. While specific agencies of the Soviet government promoted the local variety of folk dance, songs, and poetry in the republics such as Ukraine, Georgia, or Uzbekistan, other agencies caused enormous damage to their peoples, economies, and cultures by centralization, strategic miscalculations, and sometimes (e.g., in the case of the Ukrainian famine of 1932–33) purposeful acts of mass murder. Supporting the folkish manifestations of popular culture in these republics, the Soviet government in Moscow and its agents in the republics invariably suppressed nationalist movements and their cultural manifestations. While republican Academies of Sciences and Unions of Writers used the state support to cultivate the less political aspects of national traditions, public spheres in these republics were deteriorating. Before the collapse of the Union in 1991, no republic was able to create the modern institutions of free press, local self-government, or independent education. Even the central and most powerful of the Soviet republics, Russia, featured the same processes. While Russian folk ensembles flourished under the Soviet rule and Russian classical literature was promoted in schools and universities all over the Soviet Union, Russian nationalist movements were suppressed. Many directions of literature, music, visual arts, and other genres of public culture were effectively frozen. Like the poet Osip Mandelstam, many thousands of writers, artists, musicians, journalists, and architects ended their lives in the labor camps of the Gulag system. Like the writer Mikhail Bulgakov, many authors did not see their texts published in their lifetime. Like the filmmaker Sergei Eisenstein, some authors served the regime with loyalty and talent but still saw their best creations brutally destroyed. Like the composer Dmitri Shostakovich, some spent years in an unfair struggle with the system, complying with its direct orders though engaging in various forms of Aesopian writing wherever they felt they could deceive censorship. Like the writer Vsevolod Ivanov, some worked as the agents of the overcontrolling state while writing their experimental, subversive writings with no hope for publication.

Soviet cultural figures were not only objects of ideological manipulations and violent coercion on the part of the state. Its institutions were also created and run by people who shared the same characteristics – class, ethnic, and human – as those who were censored, tortured, or murdered by them. The Soviet Union's cultural elite was connected to its political elite by a tight network of family connections, friendship, and ideological loyalty. Among the prominent Soviet authors were open enthusiasts of the regime such as Maxim Gorky or Vladimir Mayakovsky, but also its quite dissidents such as Daniil Kharms, stubborn rebels such as Osip Mandelstam, and bewildered victims such as Isaac Babel. Moreover, as biographies of many of these people show, support for the regime could turn into active dissidence, or the other way around. Reflecting this complexity, the historiography of Stalinism has featured a long-lived debate between the so-called Totalitarian School and the Revisionists. It was the Revisionists who carried the day in Western universities in the 1990s though much to their chagrin, it was the Totalitarian model that would largely be embraced in post-Soviet Russia. While the Totalitarianists revealed the top-down control and coercion in Soviet society, the Revisionists emphasized the intrinsic agency of the common people and of the low-level structures of the state. After the demise of the Soviet Union, a new generation of historians has shifted the focus of these debates toward the self-disciplining practices employed in the hearts, minds, and diaries of Soviet citizens, practices which are viewed as the construction of a particular kind of subjectivity (Halfin, 2002; Hellbeck, 2006). One consequence of this body of research has been to displace to the margins the massive violence that was the definitive feature of Stalinism. While Hannah Arendt (1966) and Tzvetan Todorov (1996) see terror as the essence of totalitarian government, the new wave of historiography has

focused on those aspects of Soviet culture and subjectivity that preserve some features of freedom even under terror, such as diaries, autobiographies, and dreams. These approaches, one that focuses on violence and another that focuses on discourse, should be creatively combined. It was the state-sponsored violence of the high Soviet period (1928–53), always massive and ever increasing, which imposed self-disciplinary practices on the Soviet subjects. These practices would not have developed without the omnipresent backdrop of the gulag, where discipline was external, diaries forbidden, and human life returned to its animal origins. During this period, any member of the communist elite could be sacked, arrested, tortured, and killed at any moment and for many reasons, one of which could be insufficient loyalty. An understanding of the environment of coercion, violence, and angst is crucial for the analysis of the ideology, culture, and discursive practices of the Soviet period. The resulting complex of affects – fear, resentment, compassion, and mournfulness – was a permanent feature of the Soviet life.

Violence

While the transformation of human life had been a proclaimed purpose of the Bolsheviks from the start to the end of the Soviet project, methods of this transformation changed considerably during the long period of the Soviet rule. Stalinism relied on mass violence as the major and increasingly, the only method of the desired transformation. Focusing on these links between the enlightening efforts of the state and its murderous practices, Soviet cultural studies have overcome the traditional (particularly for the Totalitarian School) separation of politics from culture. Experience of the Soviet state, which organized life on the enormous space of Eurasia by applying mass violence to its subjects, is crucial for understanding the circular connections between cultural propaganda and political violence. The scholars of Soviet period have produced sophisticated studies of literature, art, music, theater, and other manifestations of high culture of the period. Less is known about the culture of Soviet-era torture rooms, prisons, labor camps, and special settlements. What was the cultural substance of myriads of communications that organized life and death in the huge 'zones' of violence, which were defined politically rather than geographically? How did it happen that mass violence, which we tend to imagine as a vicious circle of uncontrollable and destabilizing events – 'Terror,' as these events are known in both French and Russian – succeeded in establishing a long-living regime of Soviet socialism? As Hannah Arendt (1970) declared, violence cannot create power but actually destroys it. Symbolized and largely realized by the gulag, violence was both catalyzer and corroder of the Soviet culture.

The available estimates of the number of victims of Stalinism range between 5 and 30 millions, and even number of the official 'rehabilitations' ranges, by different accounts, from 1.2 to 4.5 million. Until now, scholars do not have anything like a full list of victims or a full list of executioners. And in the space of Northern Eurasia there are no adequate memorials, museums, and monuments, which could stabilize the understanding of these events for generations to come. However, it was the gulag camp that was the highest – the most direct, complete, and original – manifestation of the Soviet culture. Analyzing the early reports of the survivors of the Nazi and Soviet camps, Arendt (1994, pp. 233, 240, 241) identified in these writings a common tone, which she described as a 'curious air of unreality.' She argued that the incomprehensibility of the camps for their inmates, such that they frequently described their experience there as a nightmare, resulted from the anti-utilitarian character of the camps. From the common sense point of view, "neither the institution itself … nor its political role makes any sense whatsoever." Nothing offends common sense more, Arendt said, than "the complete senselessness" of the camps where the innocent suffer more than the criminal, labor bears no fruit, and crimes do not benefit their authors. This reign of pure violence needs an explanation, but the task of providing one presents an 'extraordinary difficulty.' Responding to this puzzle, Arendt presented the camps as 'laboratories in the experiment of total domination,' a goal that can be achieved only in a 'human-made hell.'

It was not the logic of production that organized the life and work in the gulag, but the logic of torture. Investigative torture has become one of the most memorable features of the Stalinist terror. However, investigative torture was applied mostly in prisons rather than in camps, where millions were kept under a different kind of torture. There in the camps, the effects of hunger, hard labor, untreated illnesses, freezing temperatures, separation from families, isolation from the world, and vulnerability to violent attacks by fellow inmates combined in an overwhelming pain that, being purposefully inflicted by the regime, should also be considered as torture. As Elaine Scarry (1985, p. 56) revealed in her classical analysis, "torture consists of acts that magnify the way in which pain destroys a person's world." Pain, Scarry argues, has a unique ability to destroy language by degrading speech to the sounds anterior to language. If pain destroys the sufferer's world, torture has an additional element: it expands the torturer's self and its self-perceived power. The pain of torture results in the dissolution of the boundary between inside and outside, conflation of private and public, and substitution of the victim's agency by that of the torturers. "The torturer's growing sense of self is carried outward on the prisoner's swelling pain."

Soviet concentration camps were torture camps, not extermination camps, and if people died in high numbers it was the result of negligence rather than purposeful intent. The gulag's primary function was to destroy the convicts' individual 'worlds,' and to substitute it by the official culture. If the need for information, as Scarry shows, is a false justification for investigative torture, the economic needs of the Soviet state were a similarly false justification for the torture endemic to the camps. Economic productivity in the labor camps was about 50% of the average level achieved by free labor in the same industries (Applebaum, 2003; Khlevniuk, 2004; Barnes, 2011). Many of the gulag's projects had no rational justification, and many have never been completed. Those that were finished, such as Belomor Canal, proved to be economically useless. The gulag managers' permanent problem was not a deficit but a surplus of labor. They did not arrest people in order to realize their projects; they invented projects in order to occupy the prisoners. The regime partially recognized the nonutilitarian nature of the camps, when it talked about their ideological, cultural, and psychological – in a word,

transformative – functions. Used universally in the prisons and camps of the gulag era, transformative torture – "re-molding and re-forging human nature," to use the language of Stalinism – efficiently turned those who were generously endowed with language, creativity, and what Arendt called 'the world,' into goners who were indifferent to everything but their next morsel of bread, or their hated neighbor.

Memory and Mourning

After Stalin's death, the enormous system of the gulag melted away with amazing ease, foreshadowing the collapse of the Soviet Union a few decades later. In 1953, there were 166 labor camps in the Soviet Union, plus a huge number of other penitentiary institutions, from prisons to special settlements. About 10 million people served time in these institutions. Almost all of them were released in 1954–56. During this and later periods, cultural memory of terror shaped into an enormous cultural formation, which encompassed different media and genres, incompatible versions of history, and various rituals of mourning. In contrast to the defeated, occupied Germany of the late 1940s, in the Soviet Union of the 1950s it was the very same institutions and personalities that had organized the mass crimes that later revealed them voluntarily. But under their control, this process of working through could not achieve closure. Ironically, Stalin's major achievement, the military strength of the Soviet Union, created a unique situation in which his regime had to analyze, exculpate, and dismantle itself. There was nobody else to do it.

In 1956, the head of the Soviet state, Nikita Khrushchev, started the de-Stalinization process. He was personally implicated in the 'repressions' that he oversaw through the decades of his service as the party leader of Ukraine and Moscow. There was nothing coercing Khrushchev to confess other than his own guilty memory of the terror and his fear of the terror's reenactment. This autonomous, self-imposed character of Khrushchev's revelations makes them unique, even unprecedented in the history of the twentieth-century violence. 'Never again' resounded as a leitmotif both in his famous report to the Twentieth Party Congress (1956) and later in his memoirs. Mourning and warning were tightly linked in his rhetoric, with the latter providing political arguments for the former. You may feel no remorse, he kept warning his peers, and you are not required to confess your own crimes; but if you do not mourn your victims, your fate will be the same as theirs. Khrushchev succeeded in transforming his milieu to such an extent that he escaped the worst: deposed in 1964; he was left in peace to live for many more years, dictated his memoirs, and was buried by his family.

Desperately in need of a conceptual apparatus that neither Marxist tradition nor the Stalinist legacy could provide, Khrushchev coined two operational concepts: 'unjustified repressions,' to embrace mass arrests, tortures, and deportations, and the 'cult of personality,' to describe the accompanying ideological practices. Both concepts served to scapegoat Stalin. 'Unjustified repressions' blamed the preceding ruler for the meaningless, unmotivated man-made catastrophe. The quasi-religious concept of the 'cult of personality' accused Stalinism of violating two fundamental tenets of Marxism – rationality and egalitarianism. These conceptual contributions were substantial, if euphemistic. If the Nazi Holocaust was ended and exposed by others, the Soviet terror was ended and exposed by its former perpetrators, who were also its potential victims. This self-victimization makes it difficult to comprehend, represent, and remember the Soviet terror. In retrospect, its agents and targets seem blurred, agency dispersed, purpose uncertain, causality cyclical, and renunciation and reconciliation incomplete.

After the collapse of the gulag, the victims of repressions were coming back from their camps as uncanny returnees. While perpetrators saw them returning to take a revenge, others imagined the fate of the repressed with horrifying details which mixed oral histories, personal fears, and literary paradigms. The whole country turned into a contact zone between the innocent victims of the gulag and the guilty survivors who managed to escape it. In 1956, Anna Akhmatova said: "Now two Russias are eyeball to eyeball. Those who were in prison and those who put them there." But these two Russias were also aware of the third, which died in the process. Shaping a zone of indistinction between bare life and state law, between repression and rehabilitation, and finally, between mourning and oblivion, this triangular relation determined the cultural dynamics of the late Soviet period.

Mourning and haunting have etched their imprints on many products of late Soviet and post-Soviet culture. A popular writer who outlived Stalinism, Ilia Ehrenburg, named this period 'the Thaw.' Tragically incomplete, the Thaw was the most successful of Russia's de-Stalinization projects. Led by poets and writers, Russia's mourners had their moment of recognition that eventuated in their unprecedented popularity during the Thaw and in the later period. Less than 10 years after Stalin's death, his heirs staged a performative act of major importance: the removal of Stalin's corpse from the Mausoleum on Red Square (1961). Defrosting three decades of Stalinism (1924–53), this remarkable decade ended in 1964, when a vigorous protest from the Communist party against Khrushchev's capricious reforms led to his dismissal. During the long, dreadful stagnation that followed (1964–85), the authorities resumed their attempts to escape from the memory of Stalinism. However, those inconsistent moves revealed as much as they obscured (Etkind, 2013; Jones, 2013). Banished from politics and transferred to culture, the work of mourning became the most sensitive ideological issue in the late Soviet period. Remembering its losses, a postcatastrophic culture lives on through the subsequent generations, as the survivors who struggle with their traumas give way to the descendants who mourn the victims of the catastrophe.

Later in the mid-1980s, Mikhail Gorbachev launched *glasnost*, a sweeping project of public truth-seeking that revealed more about the Soviet past than about Russia's present. Newly published memoirs, archival findings, and popular histories documented the processes, institutions, and personalities of the Soviet terror in unprecedented detail. The great texts of the Thaw that remained unpublished at the time or published abroad – Alexander Solzhenitsyn, Varlam Shalamov, Vasily Grossman – were all published in Russia's large print runs (Toker, 2000; Merridale, 2000; Paperno, 2009). Hundreds of memoirs and autobiographies published in the 1980s dealt with the sufferings of their authors or their parents under the

Soviet regime. In 1993, the literary historian Marietta Chudakova, then an adviser to President Yeltsin, wrote that such writing would fulfill the function of a 'Russian Nuremberg,' staged not in the courtroom as in Germany, but on the pages of memoirs. This hope failed to materialize. In fact, historians and journalists often lament the cynicism of the post-Soviet public, which instead of pluralism has learned a sad lesson about the dependency of historical truth on the changing interests of those in power. Artistic developments of the late Soviet culture, such as 'conceptualism' of Ilia Kabakov or 'necrorealism' of Evgenii Yufit, recycled Soviet symbols and ironically distanced them, contrasting these symbols with the new ambiguous contexts of consumption, death, and self-orientalization.

For the Soviet regime, an insistence on its own definition of truth was crucial; as soon as it faltered in this, it collapsed. In the twenty-first century, Russia's authoritarian 'transition' demonstrates the tortured complexity of its postcatastrophic situation, in which the past haunts the citizenry, divides the society, and limits political choice. If the second and third generations live on the same territory where the catastrophe happened; if the political regime on this territory, despite having gone through multiple transformations since the catastrophe, remains ambiguous in its treatment of the catastrophic past; if the perpetrators are not condemned, the victims are not compensated, the criminal institutions are not banned, the monuments are not built – the memory of the catastrophe acquires intense and peculiar forms. Transforming time in a way that is typical for the posttraumatic condition, the mourned and dreadful loss, the subject of remembrance, continues into the present and shapes the future. The memory of the past becomes indistinguishable from the obsessive fear of its repetition, and the dread of the future takes the shape of compulsory repetitions or creative remembrances of the past. Mourning merges with warning, shaping a temporal zone of indistinction, which combines the past and the future in a joint effort to obscure the present.

Russian and Post-Soviet Studies: Education

Abstract

Soviet education both shaped and constrained the building of Soviet socialism and of modern Russian and other societies in what is now referred to as the 'post-Soviet space.' While Soviet and international studies of Soviet education diverged sharply on some points of interpretation, almost all agreed that the Soviet educational system as launched in the 1920s, expanded in the 1930s, and consolidated in the 1940s and 1950s was fundamentally functional and conducive to modernization. Despite post-Stalinist and postwar reforms, many of the fundamental features of this system endured until the more radical attempted reforms of the late 1980s, and in many ways even after the dissolution of the Soviet Union itself in 1991. While later Russian and international authors have expressed greater skepticism about the viability and functionality of some aspects of the Soviet educational system, it did undeniably contribute, if in complex and inefficient ways, to the development of modern and literate mass societies in Russia and Eurasia.

Introduction

The vast majority of Soviet and international studies of Soviet education since the 1930s have focused in positive ways on the curricular and instructional rigor of the educational system, and its contribution to Soviet social and economic development. Almost all of this work was framed conceptually within an unproblematic model of 'modernization,' whether seen from the inside by Soviet policymakers or from the outside by sympathetic Western socialists or international experts. The official line that dominated Stalinist and postwar Soviet research argued that the history of Soviet education was a straightforward unfolding of state planning and modern development, with the Communist party-state leading the people upward into modernity and enlightenment through mass literacy, rigorous science and technology programs, scientific Marxism, and militant materialism. Perhaps ironically, this ethos of modernization was echoed in much of the contemporary Western literature, which also considered the contribution of the Soviet educational system to urbanization, industrialization, and social differentiation to be relatively direct and unproblematic. The only real point of contention was over the ultimate effects of rising literacy and the growth of an increasingly educated mass society. While Soviet scholars and educators argued that these developments would lead to the realization of true communism, and thereby establish a model for all of mankind to follow, Western scholars tended to argue that this modernization and rapid educational development would result in cultural and political liberalization on the Western model, or perhaps in the 'convergence' of East and West around a shared vision of the modern welfare state. With the exception of some émigré and dissident scholars, very few analysts seemed to consider the possibility that the Soviet educational system could have been maladaptive or dysfunctional in its ability to contribute to social and economic development, or that official accounts masked potentially serious or systemic educational problems.

This unanimity in almost all published studies of Soviet education since the Russian Revolution of 1917, and especially in studies of Soviet education since the late 1920s when rapid development began in earnest, has also obscured the distinct historical phases and sharp policy conflicts that actually characterized much of that history. In fact, the history of Soviet education is more significant for comparative and international developments than official Soviet accounts would suggest. As detailed below, the years after the Russian revolutions of 1917 were characterized by an official policy of radical progressive or child-centered education that was very much influenced by, and directly contributed to, broader international trends in educational policy. This was followed by increasingly conservative educational policies in the Stalinist 1930s and after, when the enduring foundations of the modern Soviet educational system were established. In fact, while obscured by Soviet social and behavioral science, which always claimed that Soviet developments were utterly unique (and by ideological definition more advanced than anywhere else in the world), this traditionalist restoration was actually also part of a broader international turn away from Deweyan progressive education and experimental schooling in many nations during the middle decades of the twentieth century. Many of these historical phases in educational policy, and the political and professional struggles that shaped them, have long been obscured by official Soviet historiography. While there were undeniably remarkable achievements and rapid educational expansion, the very real limits and failures of Soviet education have also long been obscured by opaque Soviet statistics and official accounts. More recent post-Soviet research, both Western and Russian, has begun to detail how, throughout its history, Soviet education was successful in many ways, and yet also heavily politicized, narrowly vocational, bureaucratically inflexible, and subordinated to the Soviet state and the Communist Party of the Soviet Union (CPSU). Ultimately, it could be argued that the inflexibility of the system, and its difficulty in adapting to the needs of postwar social and economic development, caused Soviet education to become a serious 'brake' on the viability of Soviet socialism. During the post-Stalinist period, from the 1950s through the late 1980s, various reforms were attempted in an effort to 'humanize' and differentiate the rigid and intellectually stifling system. While partially successful, the limitations of these reforms then led, in the post-Soviet years after 1991, to

attempted radical reforms, questioning of the entire Soviet legacy, and to deep system-wide educational changes in the 1990s. While the Russian state has attempted to restore funding and academic standards since 2000–01, and has continued to pursue closer links with the global educational community, serious educational problems remain in many rural and post-industrial regions, and educational conditions remain uneven in many of the other post-Soviet successor states.

Soviet Educational Experiments and Radical Progressive Education

The models for what became Soviet or socialist education were sketched out in the decades before the Russian revolutions of 1917 in response to the need for rapid social and economic development, and especially in response to the poverty and dislocations caused by World War I. The fundamental principles of Soviet progressive education included expanding the conception of education and culture to include a broad array of programs for illiterate adults, working people, peasants, and children, including early childhood care. These policies also entailed the provision of extensive public health and welfare services through educational institutions, and a radical rethinking of the nature of curriculum and instruction to bring learning 'closer to life' and industrial work. Finally, educational access and promotion were to be radically expanded to make education open to all regardless of age, ethnicity, class, or gender (Medynskii, 1925; Pinkevitch, 1929).

These early Soviet educational policies were inspired in part by European and American progressive or child-centered pedagogy, and were hailed as revolutionary by Western radicals and some educators. However, Soviet education then went far beyond Western influences in its emphasis on including previously disadvantaged populations, as well as in its increasingly dogmatic emphasis on political indoctrination (Harper, 1929). Soviet educational experiments with adult and community education were, in many ways, far ahead of their time (for an encyclopedic summary, see Kalashnikov and Epshtein, 1927–29; also Fradkin, 1990). Progressive Soviet educators sought to synthesize general and vocational education for all students in a common curriculum that was known as 'polytechnicalism,' although some vocational–technical tracking was later reintroduced. The educational experiments of the 1920s also included interdisciplinary and thematic curricula (to tie together studies of 'man,' 'nature,' and 'labor,' for example); sophisticated developmental instruction that was carefully targeted to stages of students' psychological and intellectual development (as pioneered by Lev Vygotskii and others); and efforts to foster local studies (*kraevedenie*) and culturally relevant pedagogies for national minority populations. Other innovations included student and faculty self-government, a focus on experiential learning and community service, and the curtailing of most formal assessments and criteria for promotion in the name of social equality and universal access to education. Early Soviet education was also characterized by the extensive use of Western-style child study and psychological testing, known in Soviet practice as 'pedology,' or the 'Marxist science of the child.' Resources were also invested in the mass provision of new media, libraries, and extracurricular activities for all ages, albeit with a strong political or ideological content. Finally, the 1920s also witnessed the development of modernized languages, new alphabets, primers, and comprehensive educational services for many indigenous peoples and the smaller ethnic minorities of the Soviet Union. These efforts also included ambitious programs to foster new 'national' cultures for the larger nationalities of the USSR (such as Ukrainians, Kazakhs, Uzbeks, Belarusians, Georgians, Armenians, and others; for a Western account that emphasizes modernization, see Pennar et al., 1971), yet again all within rigid ideological constraints.

Almost all accounts of these developments in the 1920s, both Soviet and Western, were extremely positive about the early progressive experiments, although some Western observers such as John Dewey (1929) and Samuel Harper (1929) were also critical of the Soviet emphasis on ideological indoctrination and their philosophical dogmatism. For all of the early Soviet educators' idealism, however, there were clearly also many internal contradictions and problems with the progressive experiments of the 1920s (Holmes, 1991). For example, while expanding access to previously disadvantaged populations, the communist regime also sought to deny or limit educational opportunity to members of the prerevolutionary elites or to real or imagined political and class enemies. This created serious social tensions, and drove many of those who could have become leading researchers, teachers, and students away from Soviet educational institutions. Public or state education was also often funded on a 'residual' basis, which meant that it was financed only after other budgetary obligations were met, even as the Soviet regime categorically prohibited any private funding from compensating for the inadequacies of state provision. Nonetheless, early Soviet progressive education, for all its utopianism and politicization, was undeniably an unprecedented and truly revolutionary experiment in the provision of mass education and culture for all. In fact, despite its internal complications and mixed successes, the image of Soviet 'education for all,' which was disseminated globally in effective propaganda campaigns, helped to inspire drives for gender equity and mass access in many Western nations as well as to inspire anticolonial educational movements and antiracism education in the non-Western world.

Stalinist Traditionalism and System Building, 1930s–50s

However, as detailed in subsequent Soviet and international research, the many problems with these early experiments also helped to discredit them, and provoked a sharp reaction in the 1930s. Soviet accounts during the period of the Stalinist dictatorship tended to blame the progressive educators for their allegedly 'anti-Leninist' errors and 'petty-bourgeois' utopianism, and even went so far as to accuse them of deliberate sabotage and counter-revolutionary 'wrecking' (Svadkovskii, 1938). As a result of these increasingly virulent attacks, many Soviet progressive educators and teachers were purged in the 1930s and their lives and work erased from the historical record, only to be partially rediscovered when Soviet archives began to open up in the late 1980s (Fradkin, 1990). Later

official Soviet accounts glossed over the distinctive progressive and experimental policies of the 1920s, obscured the sharp factional conflicts of the time, and blamed the progressive educators for their alleged impracticality and adherence to inappropriately 'bourgeois' pedagogical theory (Kuzin et al., 1980). Many international analysts simply argued that the progressive policies were not conducive to rapid social and economic modernization, and that it was thus virtually inevitable that more 'stable' and traditional curricula and instructional methods would be restored to fit the Soviet educational system to the needs of modern industrial society (Anweiler, 1964; also Pennar et al., 1971). Other Western analyses of the failure of the progressive experiments focused on issues such as the acute lack of funding that crippled the attempted reforms; popular resistance by many parents and teachers (Holmes, 1991); and the broad social support for the upward mobility opened up by the Stalinist educational restoration (Fitzpatrick, 1979). Almost all accounts since the 1930s agree that the progressive experiments became increasingly unpopular as they were accused of undermining the authority of teachers and parents, weakening curricular integrity and instructional rigor, and failing to produce the highly trained technical specialists and skilled workers needed to 'build socialism' according to Stalinist tenets. From a broader and more critical perspective, with the consolidation of the Stalinist dictatorship in the 1930s, the task became less to mobilize and empower all citizens through popular enlightenment and more to train specialists (Bailes, 1978) and to indoctrinate subjects for state-directed industrial and military development.

Struggles over educational and social policy raged on in the 1930s, and resulted in the thorough repudiation of progressive education, and the forging of a new and intensely conservative model of Soviet education. This also entailed the rejection of child-centered or developmental schooling in the name of the struggle against 'pedological deviations' and a return to a school- and teacher-centered system (Ewing, 2002). This traditionalist restoration also led to the imposition of increasingly elaborate systems of formal 'didactics,' as codified in a series of mandatory mass-produced lesson plans, textbooks, and assessments (Kairov, 1939). This Stalinist educational model was intensely traditional in curriculum and instructional methods; thoroughly politicized, especially in history and the social sciences; heavily dominated by the physical sciences and engineering; and rigidly bureaucratized and hierarchical in its administration. In fact, the CPSU prioritized control in educational administration and the social sciences, but Stalinist ideology saturated all academic disciplines, often with debilitating effects. From a more critical perspective, it could be argued that the tight system of party-state control over all aspects of Soviet intellectual and professional life that resulted from these struggles became, over the following decades, debilitating for the Soviet educational system as a whole. This was perhaps especially true in regard to the educational system's global connections and competitiveness, with near total isolation reinforced by ruthless censorship and limits on foreign travel for scholars and students.

The fundamental principles of this Stalinist or traditionalist restoration are well known through the intense international attention that Soviet education received in the postwar era, especially after the launch of the first earth-orbiting satellite (Sputnik) in 1957, which was followed by other Soviet 'triumphs' in the Cold War technology race.

The Stalinist educational system was organized through content-heavy and rigorous discipline-based curricula, and embraced traditional instructional methods such as lectures that compelled students to master and reproduce that content knowledge. The system was built upon a canon of standardized textbooks and teaching guides, and emphasized lecturing, memorization, and rigorous oral and written examinations. More positively, this system was also buttressed by a comprehensive array of teaching guides and specialized publications for teachers, school libraries, and professional development opportunities (Long and Long, 1999). An essential goal throughout was to reinforce the authority of the party-state over the entire system, of school directors and administrators over their staff, and of teachers and professors over their students. Formal assessments and rigid criteria for promotion were elaborated, with harsh sanctions for failure, lack of discipline (real or imagined), or dissidence. Many of the programs that sought to cultivate the languages and cultures of indigenous peoples and national minorities were curtailed, and many ethnic groups subjected to involuntary linguistic Russification and cultural Sovietization (Shorish, 1984), often enforced through police terror. Overall, Soviet education in the 1930s and after became increasingly rigorous, hierarchical, and formal (Konstantinov and Medynskii, 1948). Despite the damage done by Stalinist terror and World War II (Dunstan, 1997), Soviet education in this period was permeated with a spirit of discipline and order, and was closely coordinated with the Soviet planned economy and the needs of the Stalinist military–industrial complex.

There were, undeniably, real successes for Soviet education in the early Soviet and Stalinist periods, especially in raising literacy rates and building a comprehensive mass or public education system. It also seems that the traditionalist restoration was quite popular with the new Soviet elites, many professional educators and teachers, and many culturally conservative parents and officials (Holmes, 1999; Hoffman, 2003), even if some objected to its more extreme measures such as attempts to end coeducation during World War II and after (Ewing, 2010). The Soviet education system did produce unprecedented numbers of technical specialists and skilled and semiskilled workers, albeit in increasingly narrow vocational specializations. The system also proved successful at some forms of research and development, especially in mathematics, the physical sciences, and military technologies, yet at the same time built stultifying ideological filters around many disciplines and isolated researchers in 'closed' cities and secret military research institutes. As the Stalinist regime embraced conservative school practices and cultural values, it arguably also fostered compensatory legitimacy for its otherwise intensely repressive and austere version of state socialism, as demonstrated by both Soviet and émigré memoirs. Yet for all its claims to universality and unanimity, unofficial cultural and educational traditions did survive, especially among religious and national minorities, as well as among the Soviet intelligentsia in the form of unsanctioned teaching practices (Kline, 1957) and private and family tutoring.

Official Soviet research in this period was, by definition, triumphal about the onward and upward march of literacy and

enlightenment, and about the indispensable role of the leadership of the Soviet party-state (Medynskii, 1951; Petrovskii, 1953). There was also a distinct and growing tone of xenophobia, with Soviet developments depicted as both entirely self-contained and superior to all comparable international trends and technologies. The emphasis on the singular role of state power tended to obscure the more complex relations between the party-state and admittedly dependent interest groups within the teaching and academic professions, as well as the role and interests of the Soviet public, however, muted or constrained the latter (Johnson and Kortunov, 2011). In fact, one could argue that the primary mechanism to meet public 'demand' throughout these decades was the continued rapid expansion of the system at all levels, even if public opinion per se was often irrelevant in policymaking, and even as selective repression and involuntary educational tracking and career assignment continued unabated. Judgments of this system in the 1950s ranged from the triumphal official Soviet accounts to more nuanced international analyses. For example, the disillusioned Western progressive George Counts (1957) was quite harsh in his judgment of the repressive and dogmatic aspects of Soviet education, yet he also acknowledged its rigor and utility for a forced march version of modernization (see also Korol, 1958; Pennar et al., 1971). Almost all other international and émigré accounts were positive in their analyses of the system's curricular and instructional principles and its effectiveness, even if they sometimes also acknowledged its rigidity and intellectual limitations.

However, alongside the successes and popularity of the traditionalist restoration, there were severe and chronic problems with Soviet education as well. The human cost of the Stalinist terror in education and culture was devastating, and resulted in the repression of many talented researchers, educational leaders, and teachers, especially among the national minorities. While adhering to the basic principles of modernization theory, some Western authors did draw attention to the more ambiguous effects of Soviet standardized education for the development of the non-Russian peoples and languages of the Soviet Union. The system became extremely top heavy and driven by administrative interests, with little space for professional autonomy or intellectual innovation. Research in the highly specialized institutes of the Academy of Sciences was often separated from teaching in the universities and other specialized postsecondary institutions. The entire system was permeated by the belief that theory – as shaped by political ideology – should drive educational policy and pedagogical practice. Furthermore, educational institutions and professional networks were often isolated from one another through bureaucratic parallelism, as each economic sector and industry in the planned economy created its own educational and research hierarchies, which often competed for budget resources. Educational institutions and even individual teachers were closely supervised, even as some contrived elaborate and creative ways to work around or subvert party-state controls. Most significantly, the entire system was structured into narrow vocational–technical specializations that limited the development of the job skills, professional initiative, and creativity that were needed for sustainable postwar social and economic growth. These more critical perspectives only began to coalesce in the 1980s and after (Dunstan, 1992), as some late Soviet and international authors began to focus on the more maladaptive or dysfunctional aspects of the official Soviet model. In conclusion, and taken as a whole, the Stalinist or traditionalist reforms in Soviet education and research successfully and rapidly built a mass education system, but arguably did so at the price of bureaucratic rigidity, intellectual stagnation, and vocational overspecialization.

The Potential and Limits of Postwar Reforms in Soviet Education

Ironically, even as international researchers were popularizing the curricular and instructional rigor of Soviet education in the post-Stalinist period after 1953 and especially after 1957, Soviet educators began to quietly debate the inflexibility and limits of their own system. Attempted postwar reforms encompassed both more 'progressive' as well as some more 'traditional' ideas, and not all were successful. For example, an attempted reform associated with Communist Party leader Nikita Khrushchev in 1958 sought to restore the 'polytechnical' principles of the system, only this time as more rigorous and involuntary vocational tracking. This attempted reform sought to force down the educational aspirations of the Soviet public through a requirement that all students entering higher education have at least 2 years of work or production experience (Goncharov and Korolev, 1960). Significantly, this reform was essentially blocked by the combined resistance of enterprise managers, parents concerned about their children's upward mobility, and more traditionalist educators resistant to such experiments. The regime also attempted, throughout the post-Stalinist period, to strengthen 'civic-social' indoctrination in response to what was seen as growing juvenile delinquency, alienation from official ideological values, and subversive cultural influences from the West.

Other reforms in the post-Soviet period reflected the more progressive currents of the 1920s, especially the tradition of social-cultural psychology pioneered by Lev Vygotskii (1896–1934, see Vygotskii, 1991). Vygotskean cultural psychology and developmental instruction, which also received significant attention from Western researchers in the 1980s and 1990s (Wertsch, 1985), may well prove to be the most internationally significant and enduring contribution of the Soviet educational system. In a very real sense, Vygotskii's revolutionary conviction that, with a proper educational environment and sophisticated teaching, children of all backgrounds and even the disabled could be drawn up successfully through their 'zones of proximal development,' contributed to a fundamental conviction that all children could be successfully educated. Other attempted reforms in the postwar period included greater curricular differentiation; the introduction of electives for some students (Matthews, 1982); and the development of programs for talented and gifted education in the arts, sciences, and sports, as well as increased attention to disabled students (Riordan, 1988). There was also a relaxation of linguistic Russification, with relatively more flexibility offered to educational institutions in the national minority regions, and more latitude for the use of national languages. Other reforms in this period focused on shifting students out of low-quality part-time and 'correspondence' (*zaochnyi*) instruction and

into full-time academic programs. Yet it must be noted that, for all the potential of these and other ambitious reforms, they were often limited by budget constraints, or thwarted by the combined power of party-state administrators and the conservative educational establishment, perhaps especially in the various Republic-level Ministries of Education and the Academy of Pedagogical Sciences of the USSR, which later became criticized as a 'citadel of dogmatism.'

Taken as a whole, the reform movements in Soviet education from the 1950s through the early 1980s did have the effect of consolidating and extending the system, while also diversifying and enriching curricular and instructional practices. Perhaps most importantly, the Soviet educational system by the 1970s had trained a vast new body of professional teachers and researchers, and had achieved essentially universal literacy and nearly universal secondary education. Not surprisingly, official Soviet accounts focus on these achievements with little or no acknowledgment of any persistent problems or struggles over policy or practice (Kolmakova et al., 1986). Yet these achievements were, to a significant degree, gained at the expense of individual and professional autonomy, creativity, and systemic flexibility. It must also be noted that, for all of its rhetoric of equality and universality, severe inequities persisted, especially between urban and rural areas, and that literacy and educational provision lagged badly behind in many of the national minority regions. The Soviet educational system was also slow to introduce new instructional and informational technologies, and became gradually weaker and more sporadic in its provision of nonpolitical continuing education and vocational retraining.

It seems that little international attention was paid to these systemic problems, perhaps in part because sustained Western attention to Soviet education, which grew dramatically after 1957, had narrowed considerably by the early 1980s. It also seems that sustained international cooperation with Soviet educators was constrained not only by Cold War limits on travel and censorship, but also by the conservatism of many of the neo-Stalinist educators and officials who continued to dominate the system well into the 1980s.

The Crisis of Soviet Education and Its Ambiguous Contemporary Legacies

The final phase of Soviet education in the 1980s and early 1990s witnessed both radical reforms and severe systemic crises. Several attempted reforms in the early and mid-1980s sought to tighten vocational tracking and increase party-state ideological controls, but in a very real sense Soviet educated society as a whole, as well as some elements within the educational profession who were no longer willing to tolerate such reactionary policies. There was a growing sense that Soviet public education was sliding into crisis, a systemic crisis shaped by too much uniformity and rigidity and too little creativity and autonomy. This led to the emergence of a growing 'innovation movement' among educators and teachers, which emphasized Vygotskean developmental instruction, greater curricular freedom, and more child-centered pedagogy (Bazhenova, 1987; Kerr, 1990). This movement sought to humanize and democratize Soviet education, to loosen party-state controls, and foster greater professional autonomy, to recover the spirit of the progressive experiments of the 1920s (Fradkin, 1990), and especially to expand contacts with international researchers and practitioners (Muckle, 1991; also Eklof and Dneprov, 1993).

After the collapse of the Soviet Union in late 1991, the 15 newly independent republics embraced an array of educational policies. Some tried to essentially preserve the centralized Soviet system, as in Belarus and parts of Central Asia, with very uneven success. Others struggled to radically reform the Soviet system through attempted privatization and decentralization, as in the Baltic nations and the Russian Federation (Dneprov et al., 1991). Other analysts argued that the system's institutional conservatism and pedagogical inertia actually helped preserve some of its stronger features amid economic crisis and social upheaval (Webber, 2000). The reforms of the 1990s have, undeniably, unleashed a veritable educational revolution of innovation in curriculum and instruction, and finally joined together the long isolated Russian educational community with its international counterparts. Much of this reintegration into the world community of educational research and practice was facilitated by an unprecedented level of international assistance provided to post-Soviet educators and students in the 1990s, in the form of research grants and vastly expanded new educational exchanges. Yet, it must also be noted, all of the Soviet successor states experienced severe if not catastrophic crises in the funding and provision of education, and that as a result both excellence and equity suffered severely in the early and mid-1990s. It could be argued that all the Soviet republics, including the long and still-dominant Russian Federation, underestimated how entwined and interdependent both the Soviet economy and its related system of education and research really were, and how much damage would be done by its abrupt dissolution. Tragically, once post-Soviet educators and teachers were able to finally rejoin the world community from which they had been isolated since the 1920s, many lacked the financial resources to remain in the profession, or to take full advantage of the new opportunities for international cooperation or professional development. Furthermore, the economic and demographic crises that gripped the entire region in the 1990s directly threatened the health and readiness to learn of an entire generation of children and young adults. While the collapse of the Soviet Union opened up unprecedented new personal freedoms and economic opportunities for some, it also destroyed much of the socialist safety net of public education and guaranteed employment, and plunged many millions into poverty. To summarize, while the legacies of the Soviet educational system were mixed, the ultimate effects of post-Soviet reforms and educational policies remain unconsolidated, and there is a clear nostalgia in some social circles and regions for what has been lost.

Conclusions

In conclusion, Soviet education both shaped and constrained the building of Soviet socialism and of modern Russian and other societies in what is now referred to as the 'post-Soviet space.' While Soviet and international studies of Soviet education diverged sharply on some points of interpretation,

almost all agreed that the Soviet educational system as launched in the 1920s, expanded in the 1930s, and consolidated in the 1940s and 1950s was fundamentally functional and conducive to modernization. Despite post-Stalinist and postwar reforms, many of the fundamental features of this system endured until the more radical attempted reforms of the late 1980s, and in many ways even after the dissolution of the Soviet Union itself in 1991. While later Russian and international authors, perhaps especially émigré and dissident observers, expressed greater skepticism about the viability and functionality of some aspects of the Soviet educational system, it did undeniably contribute, if in complex ways, to the development of modern and literate mass societies in Russia and Eurasia. Finally, the most rigid and repressive aspects of the system were repudiated in the late 1980s and especially during the 1990s, even if the urgency of recent economic crises have obscured the urgency of such historical analysis.

Russian and Post-Soviet Studies: Environment

Charles E Ziegler, University of Louisville, Louisville, KY, USA

Abstract

Throughout the period of Soviet socialism (1917–91) environmental considerations were subordinate to state imperatives of rapid industrial development. Although there existed small enclaves of scientists and specialists committed to conservation and ecology issues, centralized authoritarian rule and state repression made environmental activism virtually impossible, while censorship obscured the scope and severity of ecological problems. Environmental groups mushroomed in the more liberal late-Soviet and early post-Soviet period, but the unrestrained capitalism and natural resource-based economy of the Putin era (1999–) relegated ecology protection to the margins of Russian politics.

Soviet Socialism and the Environment

Since the Soviet Union was the largest country in the world, the development and environmental policies enacted by the communist state impacted approximately one-sixth of the world's total landmass. Throughout Soviet history the main goal of the ruling Communist Party was economic expansion, in largely quantitative terms, with little regard for the environmental consequences of its industrial and agricultural policies. Ecological awareness did emerge in the 1960s and 1970s, roughly parallel with the development of environmental movements in Western countries, but the regime's response to environmental degradation was tepid. When censorship and political repression were relaxed in the late 1980s under General Secretary Mikhail Gorbachev (1931–), environmental movements mushroomed across the USSR. In the non-Russian republics these ecology groups often assumed nationalist overtones, accentuating demands for separation from Moscow and ultimately contributing to the dissolution of the USSR.

Under Vladimir Lenin (1870–1924), Joseph Stalin (1879–1953), and Nikita Khrushchev (1894–1971), the fixation on producing ever greater quantities of industrial and agricultural goods through the mechanism of the centrally planned economy left little room for environmental considerations. The state controlled virtually the entire economy, and at most times opposition to development goals was not tolerated. In the more relaxed political environments of the 1920s, the 1960s, and the 1980s, concerned scientists and influential cultural figures pressed the regime to be more environmentally responsible. For example, Douglas Weiner (1988) showed that conservationists worked assiduously in the 1920s and early 1930s to preserve and expand the system of nature reserves (zapovedniki) in the face of hostile Soviet developers. Ultimately the Stalinist industrialization regime, with its utilitarian view of nature, prevailed. A modest conservation movement was resurrected in the late 1950s, but it was not until the early to mid-1960s that a modern environmental consciousness was sparked by the debate over threats over Lake Baikal.

This geologically ancient lake, situated in East Siberia and holding one-fifth of the world's supply of fresh water, was threatened by pollution from a large cellulose factory, ostensibly designed to produce cord for military aircraft tires. Outraged by the danger to this natural treasure – Baikal was designated a World Heritage Site by the United Nations in 1996 – scientists and writers were joined by a few key officials in a campaign to save the lake. The Communist Party and government responded by passing resolutions creating a protected zone around Baikal and mandating the installation of water purification facilities. While in many respects a unique incident, the campaign to save Baikal was one example of the regime responding to demands from influential sectors of the public.

By the late 1960s policy makers were increasingly aware of the costs to the national economy and the dangers to public health associated with pollution, particularly of the country's surface waters. The problems were severe. Heavily polluted bodies of water included the Volga and Don rivers, Lake Ladoga, the Caspian, Black, Azov, and Baltic seas, Lake Sevan, and many others. A study prepared in the 1970s by the Institute of Geography for top government officials, and declassified in 1989, mapped out 4 million square kilometers of Soviet territory as ecological disaster areas, nearly one-fifth of the entire country. Half of the most polluted territory was located within the ecological fragile Far North and Siberia.

Egregious examples of environmental destruction were found throughout the USSR. In Central Asia irrigation for cotton production reduced the flow of the Amu Darya and Syr Darya rivers by 90%. These rivers fed the Aral Sea, a body of water the size of West Virginia. In less than three decades, the sea's level had dropped by 40 feet (13 m), its area decreased by 40%, and its volume decreased by two-thirds. The fishing industry collapsed, and dust storms blew toxic salts and agricultural chemicals across neighboring regions, elevating rates of intestinal illness, anemia, cancer, and birth defects (Pryde, 1991). Uzbekistan and Kazakhstan experienced the worst effects of the sea's desiccation; reportedly, three-fourths of the population in the Karakalpak autonomous republic in northern Uzbekistan was ill in the late 1980s, and the infant mortality rate had soared to 90 per 1000 live births. Kazakhstan also suffered from nuclear testing at the Semipalatinsk range and from pollution associated with the Baikonur cosmodrome, home to the Soviet space program. Oil-producing regions in Siberia and Azerbaijan were heavily polluted by spills and

leaks, and large areas of western Siberia were contaminated by nuclear waste from defense plants.

There were few bright spots in the Soviet environmental record. Some analysts pointed to the central thermal stations that provided heat to apartment buildings and workplaces as one advantage of the centralized economy although the system was clearly inefficient. The Soviet zapovednik system, which consisted of approximately 160 nature reserves encompassing over 54 million acres (22 million hectares), protected unique species of flora and fauna. In studying the history of the zapovedniki, Weiner (1999) found that even during the most repressive years Soviet scientists asserted some autonomy and preserved a distinct social identity separate from the party-state in their efforts to defend and promote these pristine nature reserves. Though Soviet scientists, writers, and students were neither dissidents nor civil society activists in the Western sense, they did manage to carve out a little 'archipelago of freedom' in a highly repressive state.

Similarly, in the early years of the Bolshevik regime forestry specialists continued progressive and scientific practices that had emerged in the later decades of Tsarist Russia. Although by the 1930s the Communist Party had subordinated these specialists to the political goals of the Soviet regime, through the 1920s Russian foresters resisted the peasant outlook on nature as an inexhaustible resource from God (Bonhomme, 2005).

Some progress was made in preserving endangered wildlife through inclusion in the Soviet Red Book, two volumes detailing threatened flora and fauna, which were based on the Red List established by the International Union for Conservation of Nature and Natural Resources. With the publication of the first official Soviet Red Book in 1978 lists of endangered species were compiled by ecologists and protected by law. Official industrial policy favored the use of low-waste or waste-free technologies in production, but closed-cycle processes were seldom implemented in practice. There was a modest effort at recycling paper – just under a third of all paper used was recycled by the mid-1980s. One of the most ecologically benign aspects of the Soviet economy was the absence of modern packaging, which greatly reduced the amount of solid waste generated by consumers.

Legal and Organizational Issues

Faced with a growing litany of environmental problems, the Soviet central government enacted laws on rational land use (1968), water quality (1970), mineral use (1975), forest resources (1977), air quality (1981), and protection of animal species (1981). In each case the legislation was vague and declaratory, and legal mechanisms for enforcement ineffective or nonexistent. All Soviet laws incorporated the principle of state ownership of natural resources, rejecting the concept of property rights as a motive to use resources more efficiently. While the goal of this legislation was generally the more rational use of natural resources, there were few, if any, economic incentives for conservation or economic penalties for polluting. Fees and other price mechanisms – for water usage, mineral exploitation rights (royalties), stumpage fees – were either nonexistent or inconsequential and did little to reduce massive waste and inefficiency. Polluters did not face the threat of legal action to force them to comply with environmental legislation, as did firms in the West. In any case Soviet legislation tended to be overly stringent and therefore not readily enforceable. It was more symbolic than substantial, designed to illustrate publicly the regime's commitment to environmental protection without jeopardizing production goals (Ziegler, 1987).

Environmentalists and foreign observers frequently cited bureaucratic obstructionism as a major obstacle to effective Soviet environmental policy. The incentive structure was such that each ministry and department pursued its own narrow interests, often at the expense of the common good. Moreover, there was no single agency tasked with environmental protection. In 1978, a joint resolution of the Communist Party Central Committee and the Council of Ministers restructured the State Hydrometeorological Service into a State Committee on Hydrometeorology and the Environment, with expanded powers in environmental protection, particularly in monitoring air pollution. However, this new agency had neither the budget nor the administrative authority to control pollution generated by the more powerful defense and heavy industries. Nor did the USSR enact a law mandating environmental impact studies of new development projects. Bureaucratic responsibility for environmental protection remained divided among a large number of ministries and agencies. Capital investments for air and water pollution abatement increased substantially through the 1970s, but these larger allocations seem to have had a negligible effect since modern pollution abatement equipment was often in short supply.

One of the major problems in developing an effective environmental policy was the practice of tasking the producing ministries in agriculture and industry with self-policing responsibilities in environmental protection. A problematic arrangement under the best of circumstances, the situation was made worse in the USSR by the clear bias of the planned economy toward production. Officials and managers could lose their jobs or forfeit bonuses if they failed to fulfill the plan, while the modest fines for pollution violations could easily be covered out of the plant's general fund.

The authoritarian nature of the Soviet political system contributed to its overall environmental inefficiency. Strict censorship of the media and classification of pollution data guaranteed that the public, and much of the elite, remain ignorant of the full extent of environmental degradation. The lack of a civil society led to a deep divide between the goals of the state and those of Soviet citizens (Josephson, 2013). Soviet newspapers in the Leonid Brezhnev (1906–82) era frequently carried stories of pollution violations, waste, and inefficiency, or letters from citizens concerned about threats to nature, but such reportage was carefully monitored, and often solicited, by the party and government. Critical coverage was permitted if it served state interests or if it was useful in discrediting officials who had fallen out of favor, but the full extent of environmental degradation was not made public until late in the Gorbachev era.

Environmental Activism

Autonomous ecology groups were not permitted to organize until Mikhail Gorbachev's liberalizing reforms; only mobilized

and structured forms of participation were allowed under Soviet rule. For example, nature protection societies with limited authority operated in each of the 15 republics. The All-Russian Nature Protection Society organized beautification campaigns, sponsored radio and television broadcasts, and helped organize educational programs and propaganda. Supposedly the society was empowered to comment on draft legislation, conduct factory inspections, and provide input on siting new facilities. Another mass organization with some input into the implementation side of environmental policy was the People's Control Committee, whose members could, under party and government supervision, investigate environmental violations. As with press coverage of environmental issues, these organizations only functioned with the guidance of party officials, and had no independent authority.

Formal representative institutions in the Soviet Union – the Supreme Soviet at the national level, and the union republic, region, area, district, and local soviets – were tightly controlled by the Communist Party, as were elections to these offices. The Supreme Soviet's Conservation Commission could, with party approval, criticize bureaucrats for not following party directives on environmental protection, but it was far from a representative body. Union republic governments could and did create their own environmental or nature protection agencies, but in the absence of legal or budgetary authority these structures could not effect significant change in policy.

Environmental concerns were articulated more effectively by scientists, whose professional expertise and positions gave their opinions greater authority. The most active advocates for the environment included geographers, economists, biologists, and specialists within the departments and agencies tasked with environmental protection. Scientific expertise was highly valued in the Brezhnev period, probably as part of the elite's reaction to Khrushchev's impulsive and ill-considered experiments with agriculture, and his uncritical support for the quack geneticist Trofim Lysenko (1898–1976). Environmental activism was tolerated if the principals were specialists who could speak with authority in their respective fields.

In the final two decades of the Soviet Union, specialists were able to exert modest influence on environmental policies as long as their suggestions and criticism did not challenge party leadership or the system's shibboleths, such as socialist ownership and industrial growth. The environmental efforts of Soviet scientists were augmented by support from another influential group, writers and other cultural icons. Soviet novelists such as Mikhail Sholokov (1905–84) had the stature to advocate passionately for preserving Lake Baikal. A similar coalition of scientists and writers – most prominently, the Russian writer Valentin Rasputin (1937–) and poet Evgeny Evtushenko (1933–) – played a vital role in defeating a proposal to divert Siberia's great rivers southward, to replenish Central Asian waters depleted through irrigation. This monumental project, which was shelved in 1986 after 13 years of planning and debate, ignited tensions between Central Asian advocates of diversion and Russian nationalists determined to protect Siberia's water resources.

Soviet environmental policies also suffered from the cult of secrecy surrounding the huge military establishment. Environmental problems linked to defense industries, Soviet military operations, and the nuclear industry were generally off limits to discussion, even for the most prominent scientists and writers. Defense expenditures in the late Soviet period were estimated to consume between 25 and 30% of gross domestic product, and defense-related production dominated much of the most heavily polluting industries. A dissident ecologist writing under the pseudonym of Boris Komarov (Zeev Wolfson, 1944–) sent a manuscript to the West in 1978, in which he detailed a litany of environmental disasters. A constant theme throughout the book is the Soviet government's secretive approach to ecology issues and the practice of invoking national security as an excuse for covering up the scope of pollution.

Glasnost and the Environment

The Chernobyl nuclear accident in April 1986 gave a major impetus to Mikhail Gorbachev's announced policy of greater openness, or glasnost. The Kremlin initially sought to minimize the extent of the disaster but reversed its secretive approach when European nations measured and publicized radiation levels drifting in their direction and pressured Moscow to be more forthcoming. Chernobyl heightened public awareness of the dangers to health from various forms of pollution, and in the relaxed political atmosphere of the late 1980s a large number of informal ecology groups were organized. Women concerned with the health effects on their children frequently held leadership positions in these new organizations. These late-Soviet era ecology groups were generally local in their focus, although a few umbrella organizations – most notably the Socio-Ecological Union – tried to coordinate environmental activities at the national level.

Environmental activism peaked toward the end of the Soviet period as Chernobyl and revelations about the extent of environmental degradation exposed the government's incompetence and disregard for the people's well-being. Environmental concerns in the ethnic union republics meshed with nationalism, as the Lithuanians, Latvians, Estonians, Ukrainians, Armenians, and others accused Moscow of ecological colonialism. Kazakhstan's population bitterly resented the hundreds of nuclear weapons tests that had been carried out over four decades at Semipalatinsk in eastern Kazakhstan. The Nevada-Semipalatinsk movement organized demonstrations and protests across Kazakhstan calling for an end to nuclear weapons' testing, which reportedly contributed to high rates of cancer, skin disorders, miscarriages, genetic mutation, and depression. Led by the respected Kazakh poet Olzhas Suleimenov (1936–), the movement quickly collected over 2 million signatures in favor of closing the test site. Nevada-Semipalatinsk lobbied Alma Ata and Moscow and in 1990 secured an indefinite moratorium on nuclear testing.

Beyond the immediate impact of such environmental victories, revelations of callous indifference to human life and well-being dramatically affected public opinion. The Communist Party's assertions, that Soviet socialism was morally superior to capitalism and that national minorities benefited by living under Russian tutelage, were shown to be lies. Soviet central government officials and party leaders who were responsible for locating heavily polluting industries, unsafe nuclear power plants, and nuclear testing ranges in

national homelands lost what little legitimacy remained. This erosion of public confidence accelerated the process of political disintegration.

Popular concerns with the environment found expression in the new political institutions of the reform era. In the March 1989 elections to the Congress of People's Deputies many candidates campaigned on environmental issues, and environmental complaints were voiced by numerous deputies during the opening session of the Congress in May. The smaller working body elected by the Congress, the new Supreme Soviet, formed a large and active Committee on Questions of Ecology and the Rational Use of Natural Resources, chaired by a deputy from the Karakalpak autonomous republic. The Supreme Soviet also passed an urgent resolution to promote ecological recovery, but as with previous legislation it was overly vague and largely declarative. In union republic elections in 1990 environmental issues proved equally important to voters and candidates. In the Soviet context political measures proved inadequate; a thorough overhaul of the Soviet administrative structure was needed before an effective environmental policy could be realized.

Gorbachev was clearly sympathetic to environmental concerns, as evidenced by his formation of Green Cross International following his resignation from the Soviet presidency. In January 1988 the Soviet leadership created a State Committee on Nature Protection (Goskompriroda), the first all-union government agency tasked exclusively with monitoring and regulating environmental protection. The approach to environmental protection was to be systematic rather than discretely technical, in keeping with more recent holistic approaches to environmental protection. Market-based incentives such as the polluter pays principle were to replace purely administrative measures. In addition to setting and monitoring pollution norms, Goskompriroda was empowered to conduct environmental impact studies and to develop a comprehensive program for cleaning up the environment and planning a more environmentally benign economic strategy. Although headed by committed individuals – Nikolai Vorontsov (1934–2000), a talented biologist and committed environmentalist, replaced Feodor Morgun (1924–) in summer 1989 – most of Goskompriroda's staff lacked training or experience in environmental protection. The new agency faced the monumental challenge of formulating and implementing policy in the increasingly chaotic political climate. In any event Goskompriroda simply did not have the clout to overcome embedded bureaucratic resistance.

Gorbachev's reform program shifted initiative away from Moscow, resulting in a groundswell of environmental regulations among previously disempowered republics, regions, and cities. Many local governments established permit fees and fines to raise revenues so they would not be dependent on the central government in Moscow. The result was a patchwork of fees and regulations imposed without clear reference to costs and benefits and implemented in the context of an acute economic crisis. Environmental protection in the final years of the Soviet Union reflected the general devolution of authority and chaos that characterized the newly independent post-communist states of the 1990s.

Although there were many factors contributing to the collapse of the Soviet Union, the long list of environmental problems and the failure of the Soviet state to enact and implement an effective environmental policy must be considered among the more important. The willingness of the regime to countenance the destruction of huge tracts of land, the poisoning of the air and water, and the waste of valuable natural resources, while covering up the effects of environmental degradation on the population, exposed the fundamental inhumanity of the communist system. Environmental activism laid the foundation for nationalist activism, which in turn fragmented the country into 15 separate states. In this sense an autopsy on the Soviet Union may indeed rule it death by ecocide (Feshbach and Friendly, 1992).

Soviet Legacies

Soviet legacies continued to shape environmental politics and policies for years following the collapse of the USSR. Optimism that democratization and the creation of a market economy would improve Russia's environmental record proved unfounded (Josephson, 2013). The environmental activism that flourished during Gorbachev's perestroika reforms waned in the 1990s as inflation and unemployment soared and simple survival took precedence over ecology. Russia's economic recovery after 2000 was paralleled by Vladimir Putin's (1952–) construction of an authoritarian regime that promoted the interests of the newly rich oligarchs, who had little regard for the natural environment, and favored centralized state solutions to social, economic, and ecological problems.

In this context environmental organizations functioned but did not flourish. Private sources of funding for environmental organizations were limited, and the transnational funding that had supported ecological activism in the 1990s became politically suspect in the 2000s. Greater central control and state cooptation limited civil society organizations' freedom of maneuver. Major media outlets were either under state control or exercised self-censorship – few reported regularly on ecological problems, and few Russian citizens were overly concerned about ecology issues. Environmental activists who challenged the power structure were either ignored or intimidated; antinuclear activists were charged with treason and imprisoned for publicizing 'state secrets' when they revealed instances of radioactive pollution by the Russian military. Activists opposed to the destruction of the Khimki forest outside Moscow to build a highway to St. Petersburg were harassed and severely beaten by thugs (Evans, 2012).

Much as in Soviet times, impressive environmental laws were frequently not enforced, and projects favored by powerful state and private interests were implemented with scant regard for environmental consequences. Russia's domestic and international resurgence in the 2000s was due largely to exploitation of natural resources, primarily oil and gas. As an energy superpower Russia supported national champions such as Gazprom and Rosneft, and these corporations in turn promoted Putin's goal of a strong corporatist state, generally with minimal attention to the environmental consequences of hydrocarbon production. Most of the new oil and gas fields were located in remote parts of Siberia, and their development often came at the expense of the marginalized indigenous peoples (Agyeman and Ogneva–Himmelberger, 2009).

International cooperation on environmental issues was greatly overshadowed by Russia's role as an oil and gas exporter. Russia signed the Kyoto Protocol on climate change (in 2004), but less from a genuine environmental commitment or domestic pressure than from international considerations. Moscow anticipated economic benefits from its proposed membership in the World Trade Organization, which was from the Kremlin's perspective linked to Kyoto, and was concerned with its international image. In late 2012 following the Doha meeting, Russia's government declared Kyoto had lost its effectiveness and declined to sign on to the second commitment period of the agreement.

Russian and Post-Soviet Studies: Gender

Lynne Attwood, School of Arts, Languages and Cultures, University of Manchester, Manchester, UK; and Derbyshire, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article explores the changes in the Russian understanding of male and female roles from the time of the socialist revolution in 1917 to the present day. It outlines the original revolutionary plans for altering the relationship between men and women to ensure gender equality, and then shows how these were eroded during the course of Soviet history with 'equality' periodically redefined not in accordance with the needs of Soviet men and women, but of the Soviet state. The article concludes by exploring the impact that the transition to capitalism has had on gender relations.

Introduction

Like so much else in the new capitalist Russia, gender issues have undergone enormous change in the past two decades since the collapse of the Soviet Union. While the supposed commitment to gender equality in the Soviet era does not stand up to much scrutiny, the predominant image of men and women, as paraded in the visual arts and the media of those times, was of comrades who shared the same hopes and aspirations for the communist future, who worked alongside each other in factories and farms, and, indeed, who fought alongside each other on the battlefield when this was required. While the understanding of equality underwent a number of changes during the course of Soviet history, it was always portrayed as an essential part of socialism and a defining feature of Soviet ideology and practice. The rapid transition to capitalism, however, did away with the need even to pay lip-service to gender equality. It ushered in an essentialist approach to gender difference reminiscent of that which prevailed in the West in the wake of the Second World War, when 'Rosie the Riveter' was encouraged to put down her factory tools and tie on her apron.

This article explores the changes in the Russian understanding of male and female roles from the time of the Revolution in 1917, throughout the 70 years of the Soviet era, and up to the present day. It begins by establishing the meaning of the term 'gender,' then outlines the original revolutionary plans for altering the relationship between men and women to ensure their equality, and reviews the ways in which equality was periodically redefined, not in accordance with the needs of Soviet men and women, but with those of the state. Finally, the article discusses the impact of transition to capitalism on gender relations.

Description of Terms

'Gender' refers to expected practices and behavior associated with either men or women that are not rooted in biology but are determined by culture. Western feminists have been careful to distinguish between the terms 'gender' and 'sex,' the latter referring to the biological differences between men and women. However, Soviet writers and thinkers only acknowledged this distinction shortly before the disintegration of the Soviet Union, when, in 1990, the Center for Gender Studies was founded in Moscow. The Soviet authorities always insisted, throughout the 70 years of the Soviet Union's existence, that they were committed to the establishment of complete equality for men and women. However, no attempt was made to analyze or understand the extent to which differences between men and women were the result of biology or culture. Alexandra Kollontai, the country's principal theoretician on the 'woman question' at the time of the Revolution, did come close to addressing the concept of gender (although without actually using the term), but dismissed it as an irrelevancy – indeed, as a bourgeois preoccupation. What was important, she argued, was that all people, male and female, had a real opportunity to develop their personal potential. In her words:

> Leaving it to the bourgeois scholars to absorb themselves in discussion of the question of the superiority of one sex over the other, or the weighing of brains and the comparing of the psychological structure of men and women, the followers of historical materialism fully accept the natural specificities of each sex and demand only that each person, whether man or woman, has a real opportunity for the fullest and freest self-determination, and the widest scope for the development and application of all natural inclinations.
>
> Kollontai, 1977, p. 581

Yet, despite their refusal to address the issue of gender openly, Soviet politicians were in reality very much concerned with it, and made determined attempts at different times either to eradicate or strengthen the cultural differences between men and women.

The Soviet Era

In its first decade of Soviet power, the policy of the Communist Party was to challenge traditional understandings of what were appropriate behavior and social roles of male and female. At a time when the West was promoting and preserving separate male and female spheres, Soviet propagandists were urging women to leave that female bastion, the home, and enter the public world of work and politics, until then a largely male

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10141-2

environment. Women were assured that state institutions would take over their domestic tasks. In any case, the family would become less important as people got used to living communally. Some theorists, most notably Kollontai, went so far as to argue that the family would serve no purpose at all in a communist society and in due course would simply 'wither away.'

Kollontai championed the emergence of a 'new woman' under socialism, who would embody the following qualities:

> Self-discipline instead of emotionality; the ability to value her freedom and independence, instead of being submissive and lacking in personality; the affirmation of her individuality, instead of a naïve attempt to absorb and reflect someone else's cast of mind, that of the "beloved" … no mere wife, no shadow of a man, [but] an individual, a woman who is above all a person.
>
> Kollontai, 1919, p. 29

Yet, there was no attempt to rethink the gender roles of both male and female. Women were to be incorporated into what was previously seen as the male sphere of public service, but there was no question of men taking on what were traditionally seen as women's responsibilities. In other words, women could enter the workforce, but they still had to do the housework when they came home. Articles on the organization of communes made it clear that women would still be responsible for the cooking, laundry, child care, and so on, but they would now take on this work collectively, for the commune as a whole, rather than individually, for their own families. There was also no question of them choosing not to have children. Rearing the next generation of workers was a patriotic duty, not a choice.

Widespread unemployment in the 1920s meant that few women were actually drawn into social production. This began to change in the late 1920s, when Stalin came to power. In 1929 he launched a huge industrialization drive. All workers were now needed, women as well as men, and by 1932 the number of women workers was almost double what it had been in 1928. At the same time, the pledge to free women from their traditional domestic duties was quietly abandoned. All resources were now required for industry, and if women were still willing to perform those traditional functions for free, the state would hardly fight for the right to fund them. Predictions about the demise of the family also ceased. On the contrary, the family was now held up as the 'basic cell' of Soviet society.

There are a number of reasons for this change in approach. There had already been concern about population decline, resulting largely from industrialization and modernization, before the introduction of the Plan, but the Soviet regime had insisted that the benefits introduced by socialism would encourage people to have more children. The demographic nose-dive was, then, perceived as a major crisis. It was hoped that rehabilitating the family might help reverse it. The familiarity of traditional family life might also provide some stability in people's lives in the face of such radical change. Furthermore, the family now took on a symbolic function; Soviet society as a whole was depicted as one large family, with Stalin the ultimate patriarch. Far from being an outdated institution that had no place in a communist society, the family had assumed a new significance.

Women now found themselves laboring under a 'double burden.' They were required to go out to work: there were simply not enough men to bring about industrialization at the speed or to the extent required by Stalin. However, they also had to perform their traditional domestic and nurturing functions. They were to do this with no assistance from men, nor from any services or products that could help reduce the domestic workload – given the concentration on heavy rather than consumer industry. Yet, this combination of functions was ironically hailed as evidence of women's equality, and the basis of their self-fulfillment. The 'woman question' was declared as closed. This was certainly true to some extent, since women did not have quite the same pressures as men to commit enormous amounts of time to the Party rituals. Women were much less likely to be Party members or to aim for a career in politics, for which active participation, for example, in Komsomol rituals was an essential step.

When Khrushchev came to power and launched his 'destalinization' program, the 'woman question' was partially reopened. The press on the whole continued to applaud the country's successful establishment of women's equality, but some authors now acknowledged that the real situation was more complex, and that women fell behind men in both professional and political hierarchies. At the same time, sociologists began conducting 'time budget studies' which made it clear that women devoted an enormous amount of time to domestic work, and suggested that this was a significant factor in their inferior standing in public life. There were now some suggestions, albeit tentative, that husbands might be persuaded to ease their wives' burden by 'helping' them in the home.

From the l970s, with Brezhnev in charge, there was another shift in policy. The notion that women's sense of self-fulfillment rested on their combining the traditionally female roles in the family with traditionally male roles in politics and social production began to be questioned, largely because of the seemingly intractable demographic implications: the birthrate, at least in the European republics of the Soviet Union, had remained stubbornly low. At the same time, women workers were essential in the Soviet Union's labor-intensive economy, and it was simply not possible to remove them from the workforce. Instead, there was an attempt to alter the balance between work and family in their lives and to persuade them to see the family as paramount and work as secondary. This meant that they would continue to work, but would devote less time and energy to improving their qualifications and climbing the professional ladder. Instead, they would see raising a family as their main source of satisfaction. Accordingly, a media campaign and a new school course were launched to raise the status of the family, persuade women to have more children, and encourage boys and girls to develop more traditional gender-specific traits. Not having children had never been a choice for Soviet women, but the attempted manipulation of their reproductive function now reached a new height.

Gender, although it was still not named as such, had become a major issue. Theorists now insisted that "the study of psychological differences between members of the male and female sex is an important scientific and practical question, no less important than the continuing study of their biological and physical differences" (Khripkova and Kolesov,

1981, p. 74). In the West there was also an interest in studying 'psychological differences between members of the male and female sex,' but in order to understand how those differences came about, the extent to which they challenged equality, and what could be done to overcome them. In the Soviet Union, the primary concern was to reinforce them.

When Gorbachev came to power in 1985, his program of economic reform required the 'rationalization' of the labor-intensive Soviet economy. This included the introduction of *khozraschet*, or 'self-accounting.' What this meant was that unproductive enterprises would no longer be bailed out by the government but would have to ensure their own profitability. The policy of full-employment had resulted in overstaffing enterprises, and this surplus labor had to be shed.

Inevitably, the least productive and/or the least cost-effective members of the workforce would be the first to go, and these were generally women: not only did they have to take time off work to have children, but they were also the ones who stayed at home when the children were sick. Many family benefits were paid to women through the workplace, which meant they were more expensive to employ than men (Bridger et al., 1996, p. 5). They were, as the economist Zoya Khotkina put it, 'excessively burdened by social privileges' (Khotkina, 1992, interview with the author).

Removing women from the workforce would also help disguise the widespread unemployment that was now seen as a serious likelihood. In a country that had consistently proclaimed work to be both a human right and a duty, unemployment was likely to have a considerable psychological effect on the population – and could also result in negative repercussions for the politicians who were seen as responsible for bringing it about. This could be mitigated by convincing women with small children that for them, not working outside the home did not constitute unemployment. It might also encourage them to have more children. Accordingly, staying at home was presented to women as a positive development: at last they had the 'luxury' of spending more time with their children. Sociologist Igor Bestuzhev-Lada, one of the 'experts' who regularly appeared in the press endorsing the state's policies, insisted that women only wanted to go out to work because of decades of misguided upbringing, and that given the choice, most would stay at home. They could not be considered unemployed because "the workplace for a woman is with her children. She is not without work – children are her work" (Bestuzhev-Lada, 1988, p. 21). Bestuzhev-Lada held that women should receive a state grant for this 'maternal work' that would be sufficient to ensure their financial independence. However, after the Soviet Union's collapse this clearly sounded too much like socialism, and, as we shall see, he went on to advocate self-help rather than government handouts (Levina, 1992, pp. 10, 11).

Yet, the new openness that began in the Gorbachev era meant that criticism of government policy had become possible, and articles defending women's right to work began to appear in the press. This extended even to the Communist Party's own theoretical journal, *Kommunist*. In a groundbreaking article appearing in 1989, three female scholars from the Institute of Socio-Economic Problems challenged the policy of sacrificing female workers in order to streamline the economy and improve its efficiency. This, they argued, was the motive behind the introduction of several supposed 'benefits' for women:

> In order to facilitate this female "exodus" from social production, it has been suggested that they be granted a series of privileges which will result in the reduction of their workload: the work day will be shortened, the period of paid leave to look after a new-born baby lengthened, and so on.
>
> Zakharova et al., 1989, p. 58

Within two years of this article appearing its authors had founded the Center for Gender Studies in Moscow, which, as the first feminist organization in the Soviet Union, attracted considerable attention from both Western scholars and feminist activists. It set about publishing material previously unimaginable in the Soviet Union, mounting university courses, and, with the help of grants from sympathetic Western organizations, hosting international conferences on gender issues in Soviet society.

The Post-Soviet Situation

The Soviet Union disintegrated in December 1991. In post-Soviet Russia, the tentative moves toward capitalism, which had begun in the late Gorbachev era, now proceeded at a gallop under the leadership of Boris Yeltsin. The new market economy was portrayed as the antithesis of socialism, not only in literal but also in symbolic terms, and gender was a key feature of this symbolization. Socialism, with its extensive welfare provision, was portrayed as an overprotective mother, who had prevented the development of personal initiative and entrepreneurship. The market, in contrast, emphasized the go-getting qualities traditionally associated with men, such as aggression, competition, and a willingness to take risks. The old Soviet image of men and women as partners in the building of socialism was now replaced by a much more traditional view of male and female roles: the man would go out to work and provide financial support for his family, while the woman would stay at home and provide emotional sustenance.

The post-Soviet woman was not only depicted as mother and housewife, but was also cast as sexual plaything. Pornography was ubiquitous in the new Russia. It not only spawned a mass of new men's magazines, but also invaded the pages of the mainstream press. At the same time, prostitution was presented as an attractive and lucrative career choice for women. There was also a clear expectation that women employed in the burgeoning private sector would accept the provision of sexual favors to clients as part of their job description.

The sex industry was one of the few growth areas for women in the new market economy. Unemployment was not as widespread as had been feared, partly because of the injection of government credits into the ailing and problematic mechanisms of market exit that would have created unemployment in the first place (Bridger et al., 1996, p. 40). However, there was much 'hidden' unemployment. Many people working in state enterprises were forced to work part time, or accept lengthy unpaid periods of leave; and even those who remained

in full-time employment often had to put up with long delays in the payment of wages.

Statistics are unreliable, but in the early post-Soviet period women were said to constitute more than 70% of the newly unemployed (Bridger et al., 1996, p. 51; Zoya Khotkina, 1992, interview with author). They were encouraged to see self-employment as the solution to unemployment. Bestuzhev-Lada, who had previously suggested that women be provided with grants to enable them to give up work and devote themselves to their children, now embraced the market and insisted that women should contribute to their own support, by, for example, selling home-made pies or craft items (Levina, 1992, pp. 10, 11). A similar assumption, that supposedly innate female skills and aptitudes present the most appropriate possibilities for women's self-employment, was expressed by a host of other commentators, despite the fact that most women caught up in the first wave of unemployment were engineers, technical specialists, and other professionals who were not doing traditional 'female' jobs (Bridger et al., 1996, p. 122).

While women are still not seen as employees of equal worth, they have compensated for this bias by showing greater flexibility than men at the work they are willing to do and the wages they are willing to accept. As Sarah Ashwin points out, "however biased they may be against women, employers offering low wages know that they are only likely to get female applicants" (Ashwin, 2006, p. 214). Accordingly, the fear that "unemployment [would have] a female face" has not been realized (Ashwin, 2006, p. 2).

At the same time, the resurgence of essentialist ideas about male and female roles has meant that there is a tendency to see being the breadwinner as a defining feature of being male. Indeed, some Russian commentators insist that women should not have to make any contribution at all to the family's material support (Kay, 2006, p. 166). Yet, this is only possible for the families of men who have risen to the top of the new capitalist hierarchy. Most men are in less secure employment than they were in the Soviet era, and families also have more financial obligations because the services that were provided free in the Soviet Union now have to be paid for. In her study of men in post-Soviet Russia, Rebecca Kay found that the majority embraced traditional ideas about male roles and duties and suffered considerable psychological discomfort if they were unable to fill them. There is a high level of male violence against women, other men, and themselves; around 14 000 Russian women are reportedly killed by their husbands or boyfriends every year, while 100 000 men die from suicide or murder (Kay, 2006, p. 8). Male life expectancy has also reached an astonishing low; while women live an average of 72 years, men barely reach 59 years (Ashwin, 2006, p. 1).

Male alcohol consumption, which is reportedly 10 times higher than that of women (Ashwin, 2006, p. 3), is one of the main factors behind these figures. A link has also been found between unemployment and alcohol abuse on the part of men, but not women. This might be explained by the difference in male and female domestic roles. Although women's extra family duties resulted in a 'double burden' in Soviet times and have made them less attractive employees in post-Soviet Russia, the family also provides them with a sense of meaning and purpose outside of the workplace. As Ashwin notes, this has made it "easier for them to cope with the psychological effects of unemployment or downward mobility," while men, who see their primary domestic function as providing for their families, are less likely to derive this compensatory satisfaction from family life if they lose their jobs (Ashwin, 2006, p. 216).

Yet, the sharp decline in the birthrate following the collapse of the Soviet Union would suggest that the family is not as important for women as it once was. While the low birthrate was a cause for concern throughout Soviet history, it is now seen as catastrophic – and, combined with a severe drop in the life expectancy of Russian men, has resulted in a considerable decrease in the Russian population. This has been partly offset by inward migration, mainly of ethnic Russians from the other republics of the former Soviet Union, but as Timothy Heleniak has pointed out, "Net migration…has compensated for less than half of the natural decrease" (Heleniak, 2002). According to demographer Anatoly Vishnevsky, the population shrank by 12.3 million between 1992 and 2008, and is predicted to shrink by more than another 11 million in the 19-year period between 2008 and 2025 (Vishnevsky, 2009, pp. 18, 20). Putin has described population decline as the biggest problem currently confronting Russia (BBC News, 19 May 2006).

One reason for the drop in the birthrate is that people now have more choice as to how to live their lives, including whether or not to have children. In the Soviet era the availability of contraception was severely controlled (although abortion, legal from 1955, was famously used as a form of birth control); and with the state in charge of the distribution of almost all housing, there was no guarantee that the unmarried and childless would be assigned apartments. Now contraception is readily available, and the housing market has been privatized. Accordingly, people have the means to opt out of state-promoted family life. Women's magazine *Domashnii ochag* (*Family Hearth*) explained in 2007 that a range of relationships and lifestyles is now possible, and for a variety of reasons some women prefer not to have children: they might have a strong career orientation, feel their material conditions are inadequate, be concerned about the fragility of marriage and not wish to become single mothers, or wish to spend their free time as they choose (*Sem'ya segodya*, 2007, pp. 151–156).

Some women are simply not interested in having children, as indicated by the arrival of the 'Childfree' movement in Russia. This began in the 1970s in North America to support people who chose to remain childless. In Russia it is primarily an Internet community; there is no sure way of knowing how many 'members' it has, but according to one estimate there are several thousands (Russia Today, 2011).

The Russian government is clearly concerned about the Childfree movement's potential contribution to the demographic crisis. In June 2011 a Demographic Summit was held in Moscow under the patronage of Svetlana Medvedeva, wife of the then-president Dmitrii Medvedev. Organized by the Illinois-based World Congress of Families, its publicity material expressed opposition to the Childfree movement, as well as to sexual minorities and 'radical feminists.' One of its participants, the American social scientist Steven Mosher, who is well known for rejecting overpopulation and the 'anti-natal' lobby, gave a talk on "How to create a baby-boom in Russia." His suggestions were a combination of practical measures and – reminiscent of

the old Soviet approach – propaganda aimed at schoolchildren. His three principal proposals were for the Russian Constitution to be amended so that it protected life from the moment of conception (hence, challenging women's right to abortion); for school textbooks to be carefully checked to eliminate any anti-natal sentiments and, instead, to promote the idea that "human beings are [a country's] most valuable resource," and for young couples with children to be 'sheltered' – or, in the case of families with three or more children – to be completely exempted from taxation (Mosher, 2011).

A number of financial benefits have already been introduced to encourage women to have more children. Most notably, in January 2007 Putin introduced 'maternity capital,' a one-off payment of 250 000 rubles (around € 7200), to be increased annually in line with inflation. This is paid to the mother on the birth or adoption of a second child, or a third or subsequent child if she already has more than one child and has not yet received this award. It can only be spent once the child reaches the age of three, and only for three designated purposes: the child's education, the family's housing, or to improve the mother's pension (Vishnevsky and Aakharov, 2009, pp. 32, 38, 50).

How have Russian women responded to these attempts to encourage a more traditional family orientation? As we have seen, women had very limited choice as to how they lived their lives throughout the Soviet era. Then, in the early post-Soviet period, there was an enormous outburst of feminist activity, much of it concerned with increasing this choice. A plethora of women's NGOs were set up, many with the help of funding from Western charitable organizations such as the Soros Foundation, the Ford Foundation, and USAID. However, this funding eventually dried up – as Janet Elise Johnson explains, after the terrorist attacks on New York in 9/11, "many donors, who had already grown weary of funding post-communist civil society, redirected funds towards new hotspots" (Johnson, 2009, p. 60). A large proportion of women's groups did not survive. The Center for Gender Studies that helped set up many of the now-defunct groups, however, does still exist and continues to engage in a range of academic and practical projects. It proclaims on its website that one of its aims is to raise awareness of gender issues among people directly engaged in social policy, such as members of parliament, journalists, teachers, and youth workers.

A more flamboyant defense of free choice has been staged by the self-proclaimed feminist punk band Pussy Riot, who became internationally famous after three of its members were arrested while performing a 'Punk Prayer' in Moscow's Cathedral of Christ the Savior in February 2012. One was released on appeal, but two remain in prison. Pussy Riot's 'prayer' called on the Virgin Mary to become a feminist and drive Putin out, and listed the crimes committed against the Russian people by the authorities, aided and abetted by the Orthodox church. These included homophobia ("Gay pride sent to Siberia in chains") and the promotion of traditional female roles ("So as not to offend His Holiness, women must give birth and love"). The appearance of the band members is itself a challenge to gender norms: their garish, ill-fitting clothes and balaclavas defy both traditional notions of female beauty and of the sexualized images of women which still abound in the new Russia. Pussy Riot have not eschewed family life, but also do not want it to be imposed on women. In fact, both of the imprisoned women are mothers of small children. One appealed for her sentence to be deferred until her five-year-old son reaches the age of 14 on the grounds that he needs his mother; despite the official concern about family life in Russia, the appeal was refused (*The Guardian*, 2013).

Concern about traditional family life is also a factor in the homophobic attitudes of the Russian authorities. In the Soviet Union, homosexuality clearly could not be accommodated within the country's demand for strict adherence to an officially sanctioned lifestyle. Male homosexuality was illegal and punishable by imprisonment, while lesbianism was treated as a mental illness. The more liberal atmosphere of the Gorbachev era resulted in the creation of a number of gay rights groups, many of which, like the women's NGOs, received financial support from Western organizations. Homosexuality was decriminalized by Yeltsin in 1993, although historian Dan Healey sees this as a response to pressure from the Council for Europe rather than from the gay lobbyist groups in Russia (Healey, 2004). Nonetheless, this was a major breakthrough for the movement, culminating in 1996 in the creation of a gay advice and cultural center in Moscow and the staging of a national conference attended by more than 125 delegates. However, as with the women's groups, these activities were largely dependent on Western funding and could not survive without it. Triangle, the major national lobbying organization, disappeared in 1997 when its Western funding ceased (Healey, 2004). For several years gay activism was almost nonexistent, until in 2005 Project Gay Russia was launched. It has carried out various campaigns to end discrimination and promote the rights of gays in Russia and, since 2009, in Belarus; these have included the right to freedom of assembly, and an end to the ban on gay men donating blood. Gay Russia also began organizing Gay Pride marches in Moscow in 2006. In 2006 the LGBT Network was founded, consisting of a range of regional gay support and lobbying groups.

These organizations face an uphill battle. While homophobia has always been an issue in Russia, official attitudes have been hardening. There have been repeated calls by members of the Russian parliament for homosexuality to be recriminalized and for lesbianism to be made illegal for the first time, although these have so far been rejected. Moscow Pride marches were banned from the outset by the then-mayor of Moscow, Yuri Luzhkov; and although they went ahead regardless, they have been beset by violent clashes with anti-gay protesters. In 2012 Moscow City Council banned Gay Pride marches for the next 100 years. That same year, St. Petersburg passed a law banning the 'propagandizing' of male homosexuality, lesbianism, bisexuality, and transgenderism to minors, a move which has since been adopted by other cities and regions throughout the Russian Federation. As journalist Masha Gessen explains, this outlaws anything which could be deemed to "harm […] the process of moral and spiritual development of minors, including forming among them the false perception that traditional and nontraditional relationships are socially equal." Herself a lesbian and a mother, she is concerned that for gay parents, "simply living with their children might be a breach" (Gessen, 2012).

While demographic concerns are clearly not the only reason for this resurgence in homophobia, they have played

a contributory role. As Healey explains, anti-gay legislation has been supported by religious leaders, Soviet-minded doctors, and other conservative forces who view the population decline as the gravest issue facing Russia, and blame a 'women's birth strike' and sexual perversion for 'the desecration of the national gene' (Healey, 2004). Putin himself, when asked for his view on the ban on the Moscow Gay Pride march at a press conference in 2007, explained that his attitude toward gay parades and sexual minorities was "connected with my official duties and the fact that one of the country's main problems is demographic" (Putin, 2007).

Conclusion

The 'new woman' championed by Aleksandra Kollontai turned out to be more myth than reality throughout Soviet history. She did not earn equal pay, did not have the same opportunities for professional advancement, was absent from the important decision-making political bodies, and had almost all of the domestic work to deal with. She was not an independent being but a servant of the state, serving it both in terms of production and reproduction. However, she did have a life outside the home, relative economic security, and (according to sociological studies) a sense of her own worth. Indeed, some commentators have argued that men suffered more than women in the Soviet Union, since the latter were able to use their family responsibilities as an excuse to withdraw as far as possible from the public realm, where state control was at its greatest (Funk and Mueller, 1993, p. 87). As the ultimate nanny state, the Soviet Union was also said to have deprived men of traditional masculine attributes; this led to concern that they had lost their sense of self-value and become 'feminized,' indolent, and alcoholic (Attwood, 1990).

The mad dash to the market in post-Soviet Russia turned this situation on its head. There was a revival of essentialist ideas about gender roles, and a celebration of traditional masculine characteristics that were thought to be particularly appropriate in a market economy. In the domestic realm, the role of 'breadwinner' was, in theory, restored to men. In reality, however, the new economic environment did not provide the conditions in which the majority of men could actually fulfill this role. This has contributed to a range of problems including alcohol abuse, violence, and a huge drop in male life expectancy.

While women have not been treated as equally valuable workers in the new Russia, their greater flexibility has ensured that they have retained an important role in the workplace. The family is still considered a primarily female sphere, resulting in a greater workload for women; but on the positive side, it provides them with psychological protection if they experience instability and deterioration in their work conditions.

People can make personal choices about how they live now that would have been unimaginable in Soviet days. However, some of these choices have not been welcomed by the authorities, and are, indeed, under threat. The most notable of these is the choice to reject family life in its traditional sense. With the demographic crisis seen as one of the key problems confronting Russia today, not having children is tantamount to an act of rebellion. Putin has claimed to "respect personal freedom in all its forms, in all its manifestations" (Putin, 2007), but it is hard to see how this is consistent with state pressure on childless women to procreate – and on the gay community to disappear.

Abstract

This article examines politics – the sources, structure, and operation of power – in the Soviet Union and post-Soviet Russia. The Soviet political system was a grand experiment in an alternative political and social system of applying Enlightenment principles and socialist ideology. Yet, this system generated contradictions that would be its undoing: an economic centralization that bred stagnation, a social contract trading political loyalty for accountability, and institutionalization of ethnic identities. Boris Yeltsin's political and economic reforms unraveled much institutional structure, providing the impetus and opportunity for the rise of a new elite (oligarchs) and then the reimposition of the state power under the leadership of Vladimir Putin and a new elite, the *siloviki*. Yet, the new model of state-centered corporatism faces challenges and pressure from economic strains, possible political opposition, and growing tensions with the West.

Soviet Politics: A Brief Historical Overview

To make sense of contemporary Russian politics, we have to understand what came before: the Soviet era provided institutions, ideologies, and language that Russians have not entirely escaped. To an extent Vladimir Putin's state-centered political economy does appropriate some facets of the Soviet system; for example, mobilization of popular opinion via propaganda and political or youth organizations, the use of informal patronage, a central role for state elite in the polity and economy, and a distrust of autonomous social forces. These echo Soviet political institutions and practices: an elite seeking to create a version of Western modernity with unique differences, to hold power out of distrust for autonomous social forces, and seeking a place in the global order (cf Hosking, 1997 for a comprehensive overview, also Bunce, 1999).

A combination of the strains of World War I and social tensions borne of socioeconomic change and the growth of new classes led to revolutions in February and October 1917 (March and November by the western Gregorian calendar). The first brought the end of the tsarist regime, but the unstable situation of 'dual power' – political authority split contentiously between the Provisional Government and the Petrograd Soviet of Workers' and Soldiers' Deputies – did not hold, and in October 1917 the Bolshevik Party, led by Vladimir Lenin and Lev Trotsky, took power in a *coup d'état*. In January 1918 the Constituent Assembly met in Petrograd, but Lenin quickly disbanded that body. This led to a bloody civil war from 1918 until 1922, during which the Bolsheviks reconquered most territory of the former tsarist empire (except for Poland, the Baltic countries, and parts of Ukraine and Belarus that were reabsorbed in 1939) and set up institutions that would be of supreme importance, the Red Army and the secret police (originally the Chekha, later renamed the GPU, NKVD, and then KGB). In the aftermath of the social dislocation brought on by World War I and the Civil War, the new Soviet regime instituted the New Economic Policy (NEP), a broad set of economic policies that slowed down the desired pace of economic growth and allowed some autonomy to peasants and artisans. Lenin died in 1924 after a series of strokes, and a leadership struggle ensued that would take up much of the 1920s. Eventually, Joseph Stalin emerged victorious, in part because as General Secretary of the Communist Party he could appoint his supporters to important positions in the Party. By the end of the 1920s, Stalin was the supreme leader of the Party and of the state.

Part of the struggle for power involved articulating 'proper' policy according to political needs and the tenets of Marxism–Leninism, and two crucial policies would emerge from these struggles that would shape the fate of the USSR: industrialization and collectivization. In the late 1920s, while he was allied with Bukharin and superficially supported NEP, Stalin faced three challenges. First, industrial growth was sluggish, and an independent peasantry was slowly accumulating wealth at the seeming expense of the cities and Soviet state, from which the peasants could withhold their produce. Second, the rise of fascism in Italy and its possible appearance in Germany, and Chiang Kai-shek's 1927 massacre of Chinese communists in Shanghai, raised the specter of the fledgling socialist state being dragged into a war for which its economic foundations were not yet ready. Third, to solidify his hold on power, Stalin needed to distance himself from NEP. Thus, he unleashed two radical policies designed to expand the economy, provide an alternative to Bukharin's NEP, and hopefully prepare the country for future war: rapid industrialization and collectivization of agriculture. Industrialization was not without problems and inefficiencies, given the breakneck tempo of building factories and producing increasing quantities of output. Collectivization was a disaster. The idea behind this policy was to bring peasants into collective farms run by the state or peasant collectives, and resources would be pooled and output collected for distribution throughout the country. However, peasants did not always want to join collective or state farms (*kolkhoz* and *sovkhoz*), and this resistance was met by force: the Red Army was at times used to round up peasants or to surround villages that refused collectivization. The result was a decrease in agricultural output, and to feed the cities the regime squeezed food from the peasantry – resulting in peasant hardship and even famine in parts of Ukraine in the early 1930s.

With the consolidation of Party supremacy and a centralized, planned economy bereft of private property, Stalin and his leadership gained risks as well as privileges: any negative policy outcomes could reflect very badly on the leadership. Stalin's own paranoia, and the realization that his policies and his victories in the power struggle of the 1920s gave his opponents ammunition to remove him, helped encourage Stalin to unleash 'the Terror,' waves of arrests sanctioned by Stalin and carried out by the NKVD (People's Commissariat of Internal Affairs) against elites, average Party members, some average members of society, and eventually Red Army officers and members of the NKVD itself. By the outbreak of World War II in 1939, Stalin's personal rule and authority of the regime rested on a combination of coercion, propaganda, and promises of welfare in return for political loyalty and quiescence. World War II tested the mettle of the regime and population; ultimately, the Soviet Union prevailed against Nazi Germany, although at an enormous cost of lives and materiel. After World War II, the Soviet population expected a relaxation of coercive politics as a reward for sacrifices and victory. Instead, Stalin began a new wave of coercion that began with the Leningrad Affair (repression of Leningrad's wartime leaders) and ended only when Stalin died of a stroke in 1953.

For the next 3 years, Nikita Khrushchev and Georgii Malenkov courted other elites for support, with Khrushchev ultimately prevailing. A member of Stalin's Politburo who once had been head of the Ukrainian Communist Party and who had participated in the Terror, Khrushchev initiated 'de-Stalinization' with his 'Secret Speech' in 1956, in which he blamed Stalin for the tragedies of the previous decades but highlighted the sanctity of the Communist Party of the Soviet Union (CPSU). Khrushchev also set out to improve the Soviet economy so as to compete better with the United States in the new Cold War: in particular, Khrushchev decentralized economic decision making, but his reforms brought on institutional confusion and were abandoned once he was removed from leadership in 1964. Despite this seeming political defeat, Khrushchev would leave the important legacy of legitimating reforms, especially for a generation of younger communists that included future leader and reformist Mikhail Gorbachev.

When Leonid Brezhnev assumed the post of General Secretary, he distanced himself from Khrushchev's style of leadership by proclaiming 'trust in cadres,' an implicit social contract exchanging institutional stability and modest but constant improvements in standards of living, in return for political loyalty (cf Bunce, 1983; Millar, 1985). In practice, this meant weakened accountability of Party and state officials. Most Soviets welcomed such stability after decades of turbulence under Stalin and Khrushchev, and in the 1960s and into the 1970s it seemed that Brezhnev had a formula for success: the USSR continued to hold its own in completion with the United States (which was in the throes of social convulsions of Civil Rights and protests against the Vietnam War). However, into the 1970s stagnation began to take root due to the combination of a centralized socialist system without private property, and weak accountability central to Brezhnev's social contract. Fulfillment of the Five-Year Plan and its constituent monthly plan targets was the basis for reward, and because innovation naturally entails some risk of failure, Soviet industrial managers embraced conservative economic practices. Economic troubles increased after 1979: the Soviet invasion of Afghanistan led to increased oil output by Saudi Arabia, and the ensuing oil glut reduced the petrodollar income that the Soviet Union badly needed to purchase grain and industrial machinery from abroad. In the first half of the 1980s and after a decade of détente, Ronald Reagan increased American military expenditures, including investment in technological advances such as the 'star wars' missile defense system.

In the twilight of the Brezhnev era, Soviet institutions, practices, and political culture had crystallized, even if there were growing economic and social problems that would eventually trigger reforms and the collapse of the system but that would also provide templates for post-Soviet politics and political economy (Hass, 2011). While these principles reflected elite struggles and historical contingencies (e.g., the Civil War and World War II), ideological principles were not unimportant. Previous decades of struggle and policies had been carried out in part to realize an alternative modernity constructed according to the ideas of Marx and Lenin: even if their principles were not perfectly followed, Soviet leaders still based their legitimacy on at least some manner of social security and provision and ending inequality based on ownership of capital.

The first institutional logic was a parallel dual structure of power, in which the Soviet state and the CPSU coexisted with sometimes complementary and sometimes overlapping functions. The Soviet state encompassed far more of economy and society than other modern states. In its turn, the CPSU was not merely a political party in the European mold, that is, a collection of political elites and activists sharing ideology and policy goals. Rather, it had a monopoly on political power and acted as an ideological watchdog or functional equivalent of a secular church maintaining ideological purity (Kotkin, 1995). People filling important positions in the state (such as factory managers and heads of security forces) were required to be Party members; this was the infamous *nomenklatura*, literally a 'list' of positions only filled by Party members. As the Party leadership could demand discipline and obedience in return for membership, and membership was required for important state positions, the CPSU inevitably was the true ruling body of the USSR – more specifically, the Central Committee of the CPSU, then the Politburo (the ruling body that met in the absence of the Central Committee), and at the apex the General Secretary.

A second important facet of Soviet politics was the fusion of polity and economy, as the latter was subordinated to the former through centralized state control. While this provided sources of power for the Soviet elite, it also made them vulnerable to criticism and even possible delegitimation (formal or informal), should that economy stagnate for a long period of time. Further, that centralized economy, oriented to the Five-Year Plan, grew out of attempts to control autonomous social forces that could possibly threaten Soviet power. While the 'command economy' could mobilize manpower and resources (e.g., to fight in World War II), the lack of competition and accountability bred inefficiencies that eventually led to stagnation. Yet the command economy remained the basis for a future model, with the role of the state perhaps more modest: something akin to *dirigisme*, active state participation in the economy.

Another important facet of Soviet institutions and structures was ethnic foundations to the Soviet political structure. In the 1920s, after the Red Army had regained most of the territory lost in the Revolution and Civil War, Stalin was responsible for the regime's ethnic policy, including designing new internal territorial boundaries for the USSR. Ethnic identities and conflicts had been a problem in the multiethnic Russian empire, and the Bolsheviks faced not only the possibility such tensions would resume, but also possible contradictions between ethnic and class identity. The Bolsheviks' solution was to allow (relatively) free expression of ethic identities that would still be subordinate both to an all-encompassing (if elastic) 'Soviet' identity and identities and politics of class. Further, under Stalin's direction, the Soviet government constructed internal boundaries corresponding to distribution of ethnic groups as understood in Moscow. Boundaries of 12 'republics' (with the three Baltic countries incorporated by the Red Army in 1939), and additional lower-level administrative boundaries within the RSFSR (the Russian Republic), did not correspond perfectly to the distribution of people claiming those identities. So long as the Communist Party and Soviet state could control the content, expression, and presentation of ethnic identities and relations, this would not be a problem – for the moment (cf Martin, 2001).

From USSR to Russian Federation, and 14 Other Republics

By the early 1980s it was a badly-kept secret that the Soviet economy was stagnating (aging industrial machinery and continuously disappointing harvests) and social problems were on the rise (e.g., alcoholism was increasing the male life expectancy had reached a plateau and was beginning to fall). While Brezhnev's social contract made it difficult to address these issues without threatening his rule and that of his closest allies, after his death in 1982 the time for reform was necessary – but not yet ripe. Paradoxically, the Communist Party's monopoly on political authority ultimately generated both conservative and reform forces: those who gained from the existing system or were ideologically invested in it made up conservatives, but those who desired reform could also find patrons in the Party, so long as they were quiet about desires for reform and bided their time (Cohen, 1979). And the Party did generate its reformers. Iurii Andropov, former head of the KBG (and thus privy to information about the real state of social problems), succeeded Brezhnev as General Secretary (1982–84) and implemented reforms to increase labor and social discipline. While he suffered from kidney failure and was unable to push through much change, he did sow the seeds for reform by bringing in Mikhail Gorbachev as future Party leader. After a year with Konstantin Chernenko as General Secretary (1984–85) – a sop to the Brezhnev generation – Gorbachev was elected to take the late Chernenko's position.

As he consolidated his authority, Gorbachev continued Andropov's policies of tightening discipline; for example, by having the police raid movie theaters to check for workers who should be on the job, or reducing the production of wine in an attempt to combat alcoholism. Needless to say, such tepid reforms did not work. Further, the explosion of the American space shuttle *Challenger* and the disaster at the Chernobyl nuclear power plant in 1985 drove home to Gorbachev and allies that the status quo could not continue. Gorbachev's first bold reform was thus 'New Political Thinking,' an attempt at a new détente with the United States and NATO. Reducing geopolitical tensions would not only reduce the threat of nuclear catastrophe; it would also reduce the need to invest as heavily in the military–industrial complex.

Reducing tensions was a start but would not fundamentally improve. Gorbachev faced a major obstacle to reform: ministries and officials in the command economy would block any attempts at fundamental reform. (In contrast, Deng Xiaoping could institute market reforms because the state bureaucracies had been weakened in the 10-year Cultural Revolution.) Thus, Gorbachev instituted two sets of reforms. The first was *glasnost* (openness), political reform aimed at reducing censorship and freeing up public discourse, in hopes that public criticisms would force state bureaucrats and conservative elites to reduce their resistance to change. The second reform was *perestroika* (restructuring), in which enterprises were given more autonomy from ministries in Moscow and Plan targets. Between 1987 and 1989, enterprise managers could open independent cooperatives or allow shopfloors to produce independently, after they had fulfilled production quotas for state purchases, and sell that output (goods or services) at independently set prices.

In fact, both reforms worked too well. Once it was clear that *glasnost* was a serious reform, critical public discourse expanded, but the target went beyond conservative bureaucrats to the Soviet past and possible legitimacy of communism. As well, managers and workers took the new-found autonomy of *perestroika* and expanded private production, but increasingly at the expense of production for the state and in the name of speculative profit – rather than adding value, managers would obtain deficit goods (whether raw materials or other goods) at cheap rates from the state and resell them at higher prices to other managers who needed these goods. Essentially, Gorbachev's reforms increased managers' autonomy without creating rules and institutions that would guarantee accountability and provide incentives for rational use of resources rather than speculation alone (e.g., private property, bankruptcy law, and complex financial regulations).

As economic performance continued to worsen under *perestroika*, and as *glasnost* unleashed increasing criticism of the status quo, Gorbachev introduced a third reform: *demokratizatsiia* (democratization). While Gorbachev did not intend full-blown democracy and free elections, he did allow for increased participation by independent individuals (but not independent parties) in elections to the Supreme Soviet in 1990. The combination of electoral liberalization and *glasnost* ultimately encouraged the force that would tear the USSR apart: ethnic sentiments and conflict. Despite Moscow's attempts at control, the peoples of various groups did maintain some adherence to ethnic identities, and sometimes those identities led to conflict. The first such moment was in Nagorno–Karabakh, an enclave of ethnic Armenians inside the Azerbaijan Soviet Socialist Republic. In 1988, Armenians in Karabakh began demonstrating for unification with the Armenian Republic, which the Azerbaijani leadership refused. Following this conflict, ethnic movements arose elsewhere. While many of these were

initially organized clandestinely by the KGB to co-opt and control ethnic sentiments, eventually local leaders began to act autonomously: Gorbachev's reforms were weakening Moscow's grip on the country, and officials and elites at all levels now saw the opportunity to make bids for power.

As the increasingly open media reported ethnic mobilization, a demonstration effect ensued, and a 'wave' of ethnic mobilization picked up that would bring down the USSR (Beissinger, 2002). By 1991, the three Baltic republics were calling for independence, and there were public calls for renegotiating the relations between the republics and the basis of the entire USSR. Importantly, democratization and ethnic mobilization had come to Russia: in 1991 Boris Yeltsin was elected the President of the Russian Federation (RSFSR) and could compete directly with Gorbachev, the *Soviet* leader. With the threads of Soviet polity and economy unraveling, a group of Politburo elites decided to restore order with an attempted putsch in August 1991. While the leaders of this coup were able to take Gorbachev into custody, Yeltsin remained free in Moscow to publicly mobilize the crowds gathering to defend the reformers. After several days the putsch failed, but the damage was done. Weary of further possible attempts to reverse political liberalization – and in the process to reduce their newfound privileges – the leaders of the Russian, Ukrainian, and Belarusian republics (Boris Yeltsin, Leonid Kravchuk, and Stanislav Shushkevich, respectively) – met and on December 8, 1991 signed the Belovezh Accords, which dissolved the USSR and replaced it with a weak confederation, the Commonwealth of Independent States.

Ultimately, the USSR suddenly and unexpectedly collapsed because of a perfect storm: a conjuncture of economic stagnation and reforms that created autonomy without accountability led to deterioration in living standards and created the impression that Moscow was losing control of the reform process; this image was only enhanced once liberalization of the media allowed decades of pent-up frustrations and injustices to surface and drive and increasingly critical discourse; and ethnic identities that could use ethnically-grounded institutions of state and Party (i.e., the ethnically defined Soviet republics) as the basis for autonomy vis-à-vis Moscow. Order and control in polity, economy, and society had come apart. Putting it all back together was the supreme challenge that the successors to the USSR would face.

The Yeltsin Years and a Confused Transition to Democracy and Capitalism

Rather than reform Soviet politics and political economy, Yeltsin set out to destroy the old system and build something new. As in the Soviet era (and arguably most other countries), polity and economy were closely intertwined: economic reforms reshaped the landscape of political power and the topics of discourse, and political institutions and policies engendered the reshaping of the economy in the first place.

Russia in 1992 was a country in turmoil. Price liberalization led to spikes in inflation, and privatization of state-owned enterprises was a real project rather than abstract discussion. For 1992, the executive (President Boris Yeltsin) and the legislature (the Supreme Soviet, chaired by Ruslan Khasbulatov) agreed to an uneasy truce in sharing power, with Yeltsin enjoying a year of governing via presidential decree to speed up necessary economic reforms. However, constant inflation, falling output, wage arrears, and rising inter-enterprise debt threatened to bring the economy to its knees (Gaddy and Ickes, 2002). In 1993, the truce between the two branches of government fell apart, and Yeltsin and Khasbulatov engaged in constant sparring over policies and who had ultimate political authority. The tension came to a head when a crowd marched on the Ostankino television station in September 1993; Yeltsin called in the military to quell the protests in Moscow, during which the White House (in which Khasbulatov and other members of the Supreme Soviet were taking shelter) was shelled. Yeltsin called for new elections in December 1993 to approve a new constitution and to select representatives for the Duma, the lower house of a new parliament. (At that time half of the Duma's 450 members were selected in individual mandates – direct election of the representative – while half were selected via proportional representation from party lists.) While the constitution passed, the parliamentary election had a few surprises. Yeltsin's nominal pro-reform party Russia's Choice ended up with the most seats, but the Liberal Democratic Party, headed by flamboyant Vladimir Zhirinovskii, and the Communist Party came in second and third, respectively. This resulted in a Duma that could challenge Yeltsin until the next elections in 1995. While the constitution increased the powers of the president – for example, he could dissolve the Duma and call early elections if they refused his proposal for prime minster three times, and the presidential administration had more power over economic reforms – a standoff persisted between president and legislature. The December 1995 election gave the Communist Party even more seats, and more importantly suggested that their leader Gennady Zyuganov might actually win the 1996 presidential race. While polls in early 1996 suggested Yeltsin would lose badly, by summer 1996 he had managed to improve his ratings, such that Yeltsin and Zyuganov faced off in a run-off election that Yeltsin won on claims that the Communists would turn back the clock on hard-earned reforms for the future.

Yeltsin's second term would be no less contentious than his first, and arguably less successful. The president's health continued to deteriorate, and he was now surrounded not by reformers as in the past, but by his daughter, his chief of staff, and oligarch Boris Berezovskii. Increasingly, Yeltsin appeared as distant and out of touch with reality. Even more important was the August 1998 crash of the ruble, sparked by the inability of the government to pay state debts on time. As the ruble depreciated by five times again the dollar, Russia's economy was hit badly. By summer 1999, a combination of economic pain and a sense of humiliation over NATO attacks on Serbia (long held to be a natural Russian ally) created public anger that would ultimately turn against Yeltsin and reformers. Facing increasing challenges from the Communists in the Duma, in 1999 Yeltsin recruited a seemingly competent and loyal functionary who would defend Yeltsin and his allies. This new prime minister, and eventual president once Yeltsin made the decision to step down before the end of his term, was the head of the FSB (Federal Security Services, the successor to the KGB), Vladimir Putin.

Economic reforms and Yeltsin's own political practices sowed the seeds for the eventual downfall of Russian democracy and the transformation of nascent Russian market capital into state-centered corporatism. First, Yeltsin's strength – his image as independent political actor beholden to no one – was also his weakness: Yeltsin never did create a political party to mobilize support of the public and the legislature for his reforms. His policies of economic liberalization made it difficult to create patronage structures: rewards were a one-time deal (e.g., selling off state-owned firms on the cheap), rather than a constant stream of rewards (e.g., offering positions in the state that had access to rewards, such as bribes or status). In fact, Yeltsin's basic political *modus operandi* was to employ the *lack* of structure: rather than bind allies or opponents or coerce them (except in exceptional circumstances), Yeltsin preferred to take his chances in open competition. Further, Yeltsin's economic reforms created both economic pain and a sense of economic injustice. Price liberalization led to inflation that wiped out average Russians' savings and hindered the capacity of many larger Russian firms to invest in new production or to pay wages in full and on time. Further, to speed up investment in the economy, to gain support for his 1996 presidential campaign, and to create a new bourgeoisie as a bulwark against any return to a Soviet-style economy, Yeltsin used privatization in a manner perceived as less than just. In particular, between 1995 and 1997 Yeltsin sold off potentially lucrative firms, mostly in natural resource extraction, at low prices to economic elites whom Yeltsin courted as political allies. This elite, dubbed 'oligarchs,' had made massive profits in speculation or similar economic activities under Gorbachev or the first years of Yeltsin's administration, and they looked to create their own economic empires: for example, Mikhail Khodorkovskii's oil-centered Menatep empire, or Vladimir Potanin's Interros (centered on Oneximbank and Norilsk Nickel), or Boris Berezovskii's empire in oil, aluminum, and media. While some oligarchs did invest in improving performance and profitability, in public opinion privatization was rigged in favor of a new elite that replaced the old *nomenklatura*, and democracy was undercut by a new capitalism as unequal, or worse, than that under Soviet socialism. While Yeltsin and his reform team were criticized for implementing reforms that were too radical in too rapid a manner – creating more pain and hindering the consolidation of market capitalism and democracy – those within Yeltsin's inner circle claimed that they felt they had a very short period to 'destatize' the economy, that is, to move economic resources into private hands, so that when (not if) communists or other non-liberal politicians came to power, it would be near impossible to rebuild a Soviet-style economy and polity (Hoffman, 2002).

Post-2000: The Politics of Vladimir Putin and the *Siloviki*

At the end of 1999 Boris Yeltsin stepped down from the presidency, handing it over to Putin. Using new political party Unity (Edinstvo) and slowly increasing state control of the media and key firms and sectors in the economy – for example, maintaining state control over Gazprom and Rosneft, taking control of independent television station NTV, and increasing direct management of ORT – Putin maintained the trappings of democratic procedure (i.e., elections) while undercutting the foundations for real political and electoral competition (Fish, 2005; Shevtsova, 2007). Putin was not alone in his quest for power: his regime has drawn personnel and support from the *siloviki*, security forces (literally a 'power elite') who were losers in the redistribution of property and power in the 1990s but who were trained in political manipulation, socialized to have a corporate identity and political discipline, and have few compunctions about using coercion (cf Hass, 2011, Chapter 5 for more data and sources on the *siloviki*; also Shevtsova, 2005, 2007).

If Gorbachev was a child of Khrushchev's era of reform, Putin was a child of Brezhnev's era of order, and while he has been willing to use market and democratic procedures to his own ends, he seems distrustful of both as foundations of political and economic practice (Sakwa, 2007, 2009). While Yeltsin preferred to dismantle much state structure and power, Putin and *siloviki* preferred to rebuild institutional and organizational foundations of power, including parties and the state. In short, Putin took a more corporatist approach to politics and political economy, and his strategy for consolidating power – to the extent there was a coherent, conscious 'strategy' – reveals an appreciation for building institutional hierarchy and centralizing politics around the *siloviki* in the Kremlin. In the 1999 Duma elections Putin made use of the new party Unity to gain a foothold in the Duma – rather than threatening, cajoling, or negotiating from the outside, Putin would have a tool inside the legislative branch. While Unity did not have a majority between 1999 and 2003, Putin could also use a second tool, *kompromat*, to gain political acquiescence. *Kompromat* means legally compromising materials; for example, evidence about legal violations. Given the incoherent nature of Russian laws in the 1990s, it was near impossible to make money or status without breaking some laws, especially vis-à-vis privatization or tax payments. While there were hints Putin made use of *kompromat* to gain Duma support for his policies, Putin used this tool more forcefully in his next step for consolidating political power. Before long he began his attack on the oligarchs, beginning with Boris Berezovskii and Vladimir Gusinskii. Both had extensive media holdings that Putin valued: controlling television meant controlling messages and using once again those tools of propaganda that Soviet leaders had relied upon (although until the 2010s not as bizarre as much Soviet propaganda). Putin threatened Gusinskii and Berezovskii with prosecution for supposed violations of various tax and other laws to force them to sell their media holdings to state-run corporations, such as Gazprom.

With control of television (NTV and ORT) and some newspapers, Putin could reduce criticism of his regime (e.g., of his handling of the second war in Chechnya, begun in 1999). His next step was to silence oil oligarch Mikhail Khodorkovskii, who had been critical of Putin and hinted at political ambitions. Khodorkovskii was accused of violating tax laws, and eventually he was sent to jail and his empire cannibalized, with Iuganskneftegaz, the prime jewel of Khodorkovskii's oil giant Iukos, transferred to state-owned (thus Putin-controlled) oil conglomerate Rosneft. In one swoop Putin had increased the resources and economic reach of the state, now adding

greater control of oil resources as well as natural gas (via gas monopoly Gazporm) and defeating yet another potential political opponent.

United Russia (as Unity was now named) increased its status in the Duma, gaining almost half of all seats in the 2003 Duma elections. By 2004 Putin seemed supreme: the Duma was essentially under his control, and the state was increasing its reach into the economy (especially after the creation of Rossiiskaia Tekhnologiia, a state-owned holding company that owned shares in various industrial and defense enterprises across the country, cf Hass, 2011). Rising oil prices meant increasing money for the state budget, so that Putin could buy political support by increasing pensions and spending money on public works, including repairing buildings, schools, parks, and the like that had been ignored in the cash-strapped 1990s. Corruption increased as well, possibly part of a new social compact between the political elite and the rest of the state apparatus. Russians were living better and believed they could thank Putin. However, new challenges were on the horizon. First, in late 2004 and 2005 Ukrainian citizens took to the streets of Kiev to protest perceived attempts by Putin's ally Viktor Yanukovich (and by extension, of Putin) to steal the presidential election from more Western-oriented Viktor Yushchenko. These protests, dubbed the Orange Revolution, eventually pressured Yanukovich to concede the election, and Putin faced defeat in the one neighbor the Kremlin hoped to keep in its orbit. While Yushchenko was unable to reform Ukraine's polity and economy, and Yanukovich won the next presidential election, the Orange Revolution had spooked the Kremlin elite: if organized dissent could bring down Yanukovich, were Putin and *siloviki* safe? The Kremlin stepped up corporatist control of the polity, including covert (and later overt) coercion of possible opponents and then meddling in electoral procedures to ensure not only victory but victory by a wide margin.

For the 2007 Duma elections, electoral laws were changed that made it more difficult for smaller parties to participate, and United Russia won 70% of the vote, suggesting that Putin had a clear mandate to rule. But Putin made it clear that he intended to follow the constitution and stand down, as he could only serve two consecutive terms. His handpicked successor, Dmitrii Medvedev, won the 2008 presidential election. Medvedev was perceived in some quarters as a potential reformer, but he ultimately did little in his 4 years. First, as part of the deal for stepping down, Putin remained in power as Prime Minister; second, Medvedev did not have a political vehicle like United Russia, as did Putin; and Putin, not Medvedev, was the central player among the *siloviki* networks in the Kremlin. One change that did occur under Putin was a change in the constitution to lengthen the presidential term from 4 to 6 years.

Putin had stepped aside when Russia's economy was still strong from petrodollar wealth, but by 2011 those economic gains were at risk from the global recession and decline in petrodollar income, as well as corruption and problematic economic competitiveness. In the 2011 Duma elections United Russia gained only 49% of votes and 53% of seats, a clear decline from the previous election. Putin and Medvedev decided that Putin should return to the presidency. Accusations of manipulations of voting procedures and other violations of democratic procedure were widespread in the 2011 Duma elections, and Putin's announcement of this return provoked demonstrations in Moscow that were met with police repression against demonstrators and leaders of the opposition, in particular Aleksandr Navalny.

Putin and his elite weathered the storm, although in response new laws were passed that increased the power of the state to scrutinize and control private actors: for example, foreign NGOs were subjected to greater restrictions, as a result of public claims and suspicions that many such organizations were fronts for foreign interference in Russian politics. (Given that Western NGOs had helped Yushchenko in Ukraine's 2004 presidential election, such suspicions could seem valid, even if the reality might be different.) The FSB lobbied for more control over Internet services, which was eventually granted in 2014. While a minority continued to be critical of Putin's regime for its authoritarian practices and lackadaisical approach to corruption, Putin still enjoyed popular support and the lack of an organized, legitimate opposition.

Variation in the Rest of the Former USSR

An analysis of variation in political trajectories for all former Soviet republics is a book in its own right, and this is merely a brief overview (cf McFaul, 2002; Hale, 2005; Ioffe, 2004). Briefly put, post-Soviet political change has taken three forms. The first is basic consolidation of democratic procedures and civil rights: this is the case of the three Baltic countries. The five Central Asian countries (Kazakhstan, Turkmenistan, Tajikistan, Kyrgyzstan, and Uzbekistan) have weak civil freedoms and are basically authoritarian regimes, although some are more managed and relatively peaceful (Kazakhstan) or flirted with relatively more democratic politics (Kyrgyzstan with its 'tulip revolution' in 2005). While Azerbaijan has formal elections, the country is essentially run by one family (Heydar Aliyev, and his son Ilhem Aliyev). Armenia and Moldova also have formal democratic procedures, although suspicions of corrupt electoral procedures persist, such that Freedom House and other groups are skeptical or the real degree of democratization in these two countries. Georgia's transition to democracy has been on firmer ground, relative to other post-Soviet countries, although the balance of power between the executive and legislature has been adjusted several times.

The Slavic countries of Russia, Belarus, and Ukraine are interesting not only in their own rights but also in comparison with these other post-Soviet countries. Russia, as we have seen, began with political liberalization under Yeltsin, but under Putin Russia became increasingly authoritarian. This mirrored the political trajectory of Belarus, which began with democratic reforms after 1991 but, by 1996, made a rapid slide into dictatorship once Aleksandr Lukashenka won his first presidential term. Upon taking office, Lukashenka began repressing political opposition and subjecting localities to direct control from Minsk (the capital). Economic reforms, which were slow and tepid, were essentially frozen, and Lukashenka's state maintained ownership of vast swaths of industry. Ukraine, however, has had an almost random trajectory between democracy and dictatorship (Way, 2005b).

Unlike Russia, Ukraine has had competitive presidential elections in which losers have ceded authority to winners: for example, in 1994 President Leonid Kravchuk lost and ceded authority to Leonid Kuchma, and in 2010 President Yushchenko failed to secure enough votes for the run-off election (eventually between Iulii Tymoshenko and Viktor Yanukovich) and stepped aside. In contrast, a post-Soviet Russian president has yet to step down after a loss: Yeltsin (2000), Putin (2008), and Medvedev (2012) stepped aside for hand-picked successors, and Lukashenka has not allowed real opposition in elections. Unlike in Russia or Belarus, the balance of power between the Rada (the parliament) and the presidency makes it difficult for one branch to have hegemony. At the same time, charges of corruption in Ukrainian politics abound (and have provided the impetus for waves of protest in 2004 and 2014), and Ukrainian parties have shallow roots. Thus, Ukraine still lacks organizational and institutional configurations for consolidating authoritarian rule; but the Ukrainian state and political parties are still too weak to maintain the integrity of politics and create stability in political parties and ideologies between elections.

One explanation for this variation invokes political structures at the end of the Soviet era. Much as in East European countries, the Baltic countries had existing organizations (popular front movements) that could step into the power vacuum after the collapse of the USSR. However, these organizations were not elite tools, but rather were means for political mobilization and articulation of different interests. That is, the foundations for civil society were present in the Baltics. Central Asian republics in the Soviet era were essentially run by a small elite supported by Moscow, and popular organizations were absent. When the Soviet Union dissolved, elites in Central Asia could simply take that political power for themselves without answering to broader movements. Belarus had little real popular organization, leaving a vacuum after 1991: this vacuum led to continuing economic crisis until the parliament created a presidency, and when Lukashenka won that first election, he filled the power vacuum with his patronage structure. Like the Baltics, Ukraine had an organized civic movement, Rukh, whose early participation in post-Soviet politics helped strengthen the role of the Rada and contributed to that fragile balance between executive and legislature. As we have seen, political institutions remained unstable under Yeltsin: this presented Putin with opportunities to create vehicles for elite power. However, this comparison should be viewed as preliminary; more rigorous comparative research into post-socialist political trajectories remains to be done (but see Way, 2005a).

In Place of a Conclusion: Russian Politics and the Crisis in Ukraine

As of this writing, Russian politics is certainly unsettled. Putin's regime remains firmly in power due to a combination of public support, control over media and much of the economy, and overt use of repression against perceived opposition. While Putin has enjoyed constant popular support, it is not entirely clear how much of that support is genuine and how much is manufactured through fear and propaganda, both of which might evaporate were coercion to decrease (as happened to Gorbachev in the late 1980s). The reliance on petrodollars aided Putin's consolidation of power and popularity in the first half of the 2000s, but once the global crisis of 2008 set in and the price of oil dropped, the Russian economy stagnated and one important foundation for elite control weakened. Putin's return to power in 2012 did not go as smoothly as hoped, and he has faced opposition from a segment of the public that fears a real turn to dictatorship and no longer trusts the president (Pavlovsky, 2014).

Putin's newest term became even more contentious in February 2014, when demonstrations in Kiev – the 'Maidan' protests – took a turn toward the violent. Initial attempts to end the months-long demonstration with coercion backfired, and Ukrainian president and Putin ally Viktor Yanukovich fled to Moscow. In the wake of this popular revolution against the corrupt Yanukovich regime, Kremlin-led media framed the new regime as 'fascist,' and suddenly armed military forces in ambiguous uniforms appeared in Crimea – the control of which had been a point of contention between Ukraine and Russia after 1991, in part because of the Russian naval base in the peninsula, and in part because of the sizable ethnic Russian population and popular beliefs in Russian sovereignty over the region. With the approval of the Kremlin, a referendum of dubious validity was held, in which support for unification with Russia received overwhelming support. Not long afterward, pro-Russia separatists in Donetsk and further east organized a movement for local independence and took up arms; the government was cautious at the start but escalated the military response, until full-blown engagement erupted in the summer of 2014. Circumstantial evidence points to Russian participation – for example, the provision of arms and 'volunteers' for the separatist forces – although the degree of participation is not clear. Some groups inside Russia, such as the NGO Soldiers' Mothers of St. Petersburg, claimed that Russian soldiers were wounded in Ukraine and that perhaps 1000 or more were participating in the conflict. (In response, Putin's regime branded this home-grown NGO a 'foreign agent.') In response to Putin's actions, the United States and European Union applied increasingly harsh sanctions to restrict the ability of important Russian firms to raise capital on Western markets and to restrict some Russian elites' rights to travel abroad. While the ultimate duration and effect of sanctions is difficult to predict at present, the immediate effects have been the weakening of the ruble vis-à-vis the euro and dollar and marginal reduction in GDP; combined with existing economic problems, Russia's economy is stagnating even more as a result of these new geopolitical actions. Perhaps just as important, this Western stance has placed Putin in a corner: he has relied on increasingly aggressive rhetoric and positions and ultimately has fewer resources at his command than Western leaders (although whether Western leaders have the collective will to press their advantages remains to be seen): for example, Ukraine and Europe need Russian natural gas, but Russia needs that income more desperately. Further, his increasing intransigence will make it more difficult for Putin to come to agreement with the West without appearing weak.

The consequences of the conflict in Ukraine and responses of the United States, NATO, and European Union are cloudy. The Kremlin has been ramping up anti-Western rhetoric in formal pronouncements and media propaganda, but there is as yet no apparent increase in coercion against critics or potential opponents – and the author did not notice much apparent tension when he visited Russia in summer 2014. Yet, this does not deny the possibility that Putin and his regime are feeling increasing international isolation and are fearful of increasing social tensions at home, especially if international sanctions and expenses of the Crimean annexation and support for the Ukrainian separatists continue to burden the economy. Putin's use of some Soviet traditions – propaganda, active state participation in the economy to subordinate much of that economy to the Kremlin's needs and power, mobilizing parties – served him well in consolidating *siloviki* positions, but 'Putinism' seems incapable of facilitating the fundamental transformation necessary to give Russia a dynamic twenty-first century economy, polity, and society. While economic stagnation by itself did not bring down the USSR, it was a contributor; the Soviet economy, and thus polity, was dependent on petrodollars; and authoritarianism ultimately bred resistance, especially when its leadership appeared increasingly out of touch and irrational. Whether Putin and *siloviki* will strategically alter course or fall into similar traps remains to be seen – the confusion and contention of post-Soviet politics is far from over.

Abstract

This article discusses the distinctive characteristics of Soviet society. It addresses the main social cleavages in Soviet society: status, class, ethnicity, and gender. The article also presents key features of Soviet culture, trust networks, and deviance. Finally, it focuses on issues related to post-Soviet society: inequality, market reform, organized crime, and democratization.

Soviet society is part of a broader and more generic category of society called 'state socialism.' Comparative historical research contrasts state socialist societies with feudal, capitalist, and postindustrial ones. Soviet society most precisely expresses the characteristics of state socialism because the Soviet Union initially adopted this type of society decades before other countries and then exported it throughout the globe. Soviet society and, later, its related state socialist satellites in the Eastern Bloc held a key role in the world system during the twentieth century, but finally collapsed in 1991.

Main Characteristics

Soviet society was influenced by the writings of Karl Marx and his followers. Marx claimed inequality in capitalist societies comes from the social relations of production and, specifically, whether persons own the means for production or not. Therefore, unlike capitalist societies, Soviet society had no private property aside from household and personal items, such as combs, automobiles, etc.; productive resources, such as housing, factories, land, etc. were owned collectively. According to Marxist thinkers, a dictatorship of the proletariat over productive resources and other societal organizations would be necessary as a transitional phase before reaching the ideals of communism. When the Bolshevik Revolution occurred in 1917, the new Soviet leaders did not have blueprints for what this communist future would look like after the transitional phase because very little had been written about it.

In the Soviet Union, the Communist Party and the government bureaucracy, the 'party-state,' coordinated the control of all aspects of society, including productive resources, the political structure, and societal organizations. Far from Lenin's predicted withering away of the state as the transition progressed, the official bureaucracy eventually overshadowed the more ideological focus of the Communist Party and elaborated its logic throughout society by the 1970s. The disjoint between the ideals of communism and the bureaucratic reality led scholars to call the reality 'actually existing' state socialism (Bahro, 1978) to distinguish it from the ideology of communist leaders. As an example of this heavy-handed bureaucracy, Soviet citizens even had limited freedom of movement within the Soviet Union.

Research on Soviet Society

The social scientific study of Soviet society did not reach its full potential during the Soviet Union. Social science in capitalist countries was heavily influenced by the politics of the Cold War. Capitalist governments had an interest in staying abreast of events and trends in the Soviet Union and granted funding for research on it. But, scholars had a hard time accessing objective and systematic data for their studies. Soviet authorities separated foreign academics from ordinary Soviet citizens, making it difficult to undertake their studies. This isolation encouraged academics to use publicly available information from officials and other elites as an alternative to conduct their research. Not surprisingly, sociology and anthropology were underrepresented in the field of Soviet studies, while research about elite politics (most precisely expressed in 'Kremlinology') and economics had a greater presence.

Not only was social science in capitalist countries unable to develop fully, but Soviet scholarship on Soviet society was limited too. It was not until the 1960s that sociology was even recognized as a legitimate discipline in the Soviet Union. After sociology's professionalization, academics found it hard to conduct research projects on current trends in Soviet society. Non-Marxist sociological perspectives of Soviet society were forbidden and even Marxist interpretations of current trends were potentially suspected because they could contradict official ideology and policies. Moreover, one of the main tools of social science, large-scale survey research, did not develop until quite late. Part of this delay stems from the political tradition of letter writing in the Soviet Union. Whereas the ruling classes in some capitalist societies rely on monitoring public opinion through large-scale surveys, Soviet authorities encouraged citizens to write personal letters to newspapers and government bodies about their concerns and opinions. However, these limitations in the social sciences of capitalist countries and the Soviet Union did not stop Soviet studies from generating considerable insights into Soviet society.

Soviet Stratification

Despite its official ideology, the Soviet Union was not a classless society; Soviet society was deeply stratified throughout its existence. But, stratification in the Soviet Union was comparatively less unequal than in many of its contemporary capitalist

societies. The party-state redistributed resources among various societal sectors, organizations, and groups according to its ideology. Official ideology, among other things, promised full employment and welfare, including vacations, health care, and education, to all citizens. The party-state virtually stamped out illiteracy and social privilege based on intergenerational transfers of wealth in a country that had been rural with a ruling aristocracy. While state socialism diminished absolute levels of poverty in the Soviet Union over time, many groups by the 1980s lived modestly compared to persons in structurally equivalent positions in contemporary capitalist societies.

There was also upward mobility for members of the working and agrarian classes during the Soviet Union. Climbing the social ladder partly occurred through improved educational opportunities for citizens during Soviet-style modernization (Fitzpatrick, 1979). The promise of education, health care, and other social services to citizens created position vacancies for qualified persons too. Another factor in the mobility of persons with modest family origins came from the downward mobility of other classes, like the old intelligentsia and rich peasants, through brutal purges and emigration. Other upward streams happened because the regime valorized agrarian and industrial work. The value placed on occupations, such as dairy worker and lathe operator, was not just talk and ideology. These occupations received salaries relatively commensurate with higher skilled occupations, such as teacher and doctor.

Status

While the regime did level these kinds of inequalities to some degree through 'social homogenization' policies, status and power still deeply stratified Soviet society. Elaborated bureaucratic control over society created fine-grained occupational niches and encouraged professional regression to 'pure' kinds of work. Occupational prestige had similarities to capitalist societies, with white-collar jobs enjoying greater status than blue-collar ones (Babushkina and Shubkin, 1986). But, even lower-status work, such as metallurgy and carpentry, that had previously revolved around various jobs formalized into elaborate professions that granted credentials, advancement, and seniority to persons. The privileges associated with certain kinds of white-collar occupations also persisted. So, for example, doctors', teachers', and journalists' children continued to have access to better education, health care, and services through their social networks and socialization. Persons with these backgrounds translated their social and cultural capital into better opportunities for their careers and, ultimately, occupational status in Soviet society.

Another important factor in Soviet stratification – especially at the top of the hierarchy – was power. The Communist Party held the prerogative to promote, appoint, and dismiss personnel for a list of top positions called the 'nomenklatura' (around 750 000 jobs in the Soviet Union). With only about 7% of society as members of the Communist Party, Soviet citizens often joined the party to further their careers because it had such a determining role for advancement. The centralization of control in Soviet society gave the nomenklatura considerable privileges as well. The nomenklatura and their families had access to higher quality products and services than the rest of society. The separation of the Soviet ruling class from the masses was present from the beginning of the Bolshevik Revolution, but became more conspicuous over time. Ordinary Soviet citizens tried to attach themselves to members of the nomenklatura in patron–client chains to improve their situation. By the Brezhnev era, Soviet society was riven by clientelistic relations that fragmented the stratification system into personal tyrannies of elites and their followers (Voslensky, 1984; Rigby and Harasymiw, 1983).

Class

Even though the party-state abolished most forms of private property, there was evidence of a class system operating in the stratification hierarchy. Class analyses often came from abroad or the near abroad in the state socialist societies of the Eastern Bloc because scholars had greater freedom and an audience for their critiques. According to Konrád and Szelényi (1979), the new dominant class of state socialism did not base its power on ownership of the means production, but on its political position to redistribute resources. This class of managers extracted surplus value from the production of workers. As state socialism was the dictatorship of the proletariat, it legitimated its dominant position by claiming centralized control over resources was for the good of all citizens. Expressing this ideological concern for workers, bureaucrats from government and enterprises had strong relationships with the leaders of labor unions and very rarely did ordinary Soviet workers organize in contentious activity against their political masters. Thus, the new dominant class of state socialism was partly able to extract surplus value from labor by co-opting the leaders of labor unions into its ranks.

At the same time, workers had considerable control over their labor on the shop floor because management was focused more on resource flows external to the firm than supervising work inside (Burawoy and Lukács, 1992). The lack of supervision over workers led to chronic problems of foot-dragging, absenteeism, and drunkenness at Soviet workplaces. In less despotic times and places, workers would also use their places of work during regular working and after hours for their own entrepreneurial activities in 'the second economy' (see Stark, 1986). The use of official resources to produce goods and services that could be sold for profit in an unofficial marketplace became widespread and almost tolerated by the 1980s. This contradictory set of class relations between managerial and working classes is encapsulated in a saying of Soviet workers: 'Management pretends to pay us and we pretend to work for management.'

Soviet Ethnic and Gender Relations

Along with status and class, Soviet society had other important social cleavages. The Soviet Union was ethnically heterogeneous with 140 different nationalities officially recognized. The party-state recognized some of these differences with the formal institutions of federalism and other territorial designations. Even within the 15 republic nationalities, there were numerous unique ethnic groups that existed without formal territorial recognition. Soviet authorities tried to diminish

ethnic differences by creating a new Soviet person, 'homo Sovieticus.' The party-state exported Russian language and culture to different parts of the Soviet Union as a 'civilizing' force to create this new Soviet future because Russia was the political center of Soviet nations and there were still legacies of Russian chauvinism from the Russian Empire. Authorities promoted, with varying levels of vigor, Russian language education as a way to achieve the merging of nations. Leaders of different Soviet national republics often conducted official activities in Russian and, in the case of Central Asian nations, even had their native languages adopt Cyrillic-based alphabets.

Despite efforts to merge Soviet nations, the party-state was sensitive not to force an ethnically diverse society into a Russian-only language policy and promoted bilingualism for different ethnic groups. Ethnic minorities had considerable rights to preserve cultural practices that did not contradict Soviet ideology (see Mandel, 1985). Moreover, ethnic minorities were prominent in top positions of their own republics and regions. The achievements in promoting diversity and granting self-determination did not mean that Soviet society had eradicated discrimination and prejudice. Conflict between different ethnic groups in the Caucasus and Central Asia erupted into violence in the 1980s. In the European part of the Soviet Union, many persons from Slavic and Baltic ethnicities continued to hold prejudices and to engage in everyday forms of discrimination against non-European minorities.

The status of women in Soviet society noticeably improved from the prerevolutionary era. Marxist thinkers saw women subordinated in capitalist societies because many women engaged in unpaid labor as wives and mothers in the household economy. Soviet authorities encouraged women to participate in the labor force partly for this reason and partly because there were shortages of males. Losses in World Wars I and II created unbalanced sex ratios with significant deficits of males. Soviet women achieved high labor force participation rates decades before women in capitalist countries. Still, sex segregation of work was considerable with men hoarding more high status positions. Sex segregation was particularly noticeable because women achieved higher levels of education without analogous rates of change in better quality jobs (Gruzdeva and Chertikhina, 1986). Moreover, Soviet women continued to work more than men in the household economy. This situation is similar to the position of working women in contemporary capitalist societies, who often work the 'second shift' at home while their male partners have more time for leisure.

Soviet Culture, Networks, and Deviance

Soviet society had a distinctive culture that accompanied its social structures. There were very few social scientific studies of daily life in the Soviet Union because the barriers were great for international researchers to immerse themselves in Soviet society and ethnography was not a prominent research tradition in Soviet social science. A notable exception was Humphrey's (1983) study of a collective farm that documented the daily rituals and struggles of rural workers. Recent historical work has been reconstructing the distinctiveness of Soviet culture through archival research. Kotkin's (1995) study of Magnitogorsk during Stalin's reign uncovered how ordinary Soviet citizens developed a unique way of 'speaking Bolshevik' to make claims on authorities and others. Further research on Soviet culture has established other everyday forms of resistance against authority. The findings of cultural research underscore that Soviet society had more avenues for resistance than research on formal organizations and social structures claimed.

Much like capitalist countries, the Soviet Union had informal social networks that interpenetrated the formal organizations dominating their society. One type of these relations was called 'blat' in Russian and helped persons overcome the shortages and formalism associated with Soviet bureaucracy. Persons used trust networks to acquire resources that were difficult to obtain, such as household items and good job opportunities. But, these interpersonal networks were not 'one-off,' asymmetric relations that scholars have described in capitalist societies. Instead, blat required more emotional investment and reciprocity to be effective (Ledeneva, 1998). Also, in contrast with some capitalist societies, these trust networks had an instrumental quality rather than one of fostering a civil society. Given the deficit economy and single-party rule, blat relations had an economic rationality in them and lacked the demand to depoliticize interpersonal ties.

Even though blat relations can be used for corrupt purposes, they were distinct from structures surrounding crime and deviance in the Soviet Union. As bureaucratic control expanded throughout Soviet society, so too did the activities deemed to be illegal and deviant. Economic and political activities, such as speculation and political opposition, had harsh penalties that sent millions of perpetrators to the Gulag (see Barnes, 2011). During Stalin's reign, the mere suspicion or even appearance of such wrongdoing was enough for brutal punishment. State repression against its citizens lessened after Stalin's death, but fear of the Soviet penal system drove criminal activity deeper underground. Criminal groups developed elaborate structures and codes to stop detection from Soviet authorities. Among other deviant activities, criminal groups played an important role as enforcers and participants in the second economy and other market-based ventures because profit-making was illegal until the late 1980s. As we shall see, the position of criminal groups in these market structures put them at an advantage during the transition to a market-democratic society.

Post-Soviet Society

Paradoxically, one of the strengths of Soviet society, its ethnic diversity, played a large role in its demise. Popular mobilization of different ethnic groups called for greater national self-determination and grew precipitously after the breakup of the Eastern Bloc in 1989. Starting in the Baltics and then diffusing to other republics, ethnic leaders harnessed massive popular action for independence from Soviet rule. At the end of this wave of protest, the dominant Slavic republics finally declared independence and the Soviet Union collapsed in 1991 (Beissinger, 2002). The rise in contentious gatherings may be related to Soviet citizens recognizing that the standard of living in Western European and North American capitalist societies was higher than what they were experiencing. This diminished

the legitimacy of the party-state and its weakened position debilitated members from stopping popular discontent.

One line of inquiry in post-Soviet studies looks at what happened to the nomenklatura and other elites since the collapse. Have they been able to stay in power or have new elites emerged? Large-scale studies in Eastern Europe and the former Soviet Union address whether the nomenklatura has been able to stay on the top of the postcommunist stratification system (Eyal et al., 1998). Part of the interest in this question is related to the presumed expansion of the polity that should come with adopting democratic institutions. There is significant variation among the 15 former Soviet republics, but overall the evidence suggests that the nomenklatura has been able to maintain its elite positions in a new market-democratic society. Where there has been a changing of the guard, like in Russia, the circulation of elites has seen shallow recruiting from the 'second rung' of the Soviet elite (Hanley et al., 1995).

Assessing other 'winners' and 'losers' of the transition to capitalism has been the focus of further studies. The rapid, 'shock therapy' policies that most of the former Soviet Union adopted to create market-based economies had a deleterious effect on economic growth and inequality during 1990s. The returns in the stratification system for women, entrepreneurs, and the educated were still less than those for persons with political power in 1990s' Russia (Gerber and Hout, 1998). Critics of this rapid approach to reform often point to another state socialist society, China, and its economic prosperity as evidence that gradual policies are a better route to capitalism (Burawoy, 1996). Such comparisons imply that state socialist societies would be better off creating capitalist economies without reforming their political structures because the party-state is still intact in China.

Another line of inquiry in post-Soviet studies has been assessing economic reforms and the effects of mass privatization and rapid marketization on society. The very foundations of the social sciences tried to grapple with an analogous large-scale economic change. Marx, Weber, Simmel, and Durkheim were primarily concerned with understanding a similar question posed by the former Soviet Union's transition to capitalism: What happens when a market economy emerges? Burawoy and Krotov (1992) argue Russia's transition to capitalism has similarities to previous ones and find its economy in a 'merchant capitalism' phase – a developmental state prior to a capitalist mode of production. Other scholars point to distinctive features in the emerging post-Soviet market economy. Hass (2011), for example, argues that theories imported to guide and to analyze market reform in Russia ignore the historical development of various institutions that ordinary Russians have adopted. Practices and structures developed in the post-Soviet economy, such as alternative monies and financial–industrial groups, reflect specific historical circumstances and not just what previous theory predicts.

Another distinctive feature of post-Soviet society has been the expansion of violent entrepreneurship (Volkov, 1999). Criminal groups were in a good position to take advantage of market opportunities that emerged in the 1990s because some of them were already working in the second economy during the late Soviet period. Additionally, the contraction of the military after the Cold War made many specialists in violence and would-be soldiers open to using their knowledge for entrepreneurial endeavors. The demand for protection was also high because the government did not have the capacity to protect the rights of a growing population of new property owners (Varese, 1994). The success of criminal groups in providing protection and extracting tribute from clients eventually helped them get a foothold in various levels of government because these activities have many similarities with the main functions of a modern state.

The economic decline and growing chaos of most of the former Soviet Union during 1990s created conditions for greater control over the economy and polity. With the notable exception of the Baltic countries, much of the former Soviet Union has rolled back freedoms in the economy and politics that some citizens enjoyed during the 1990s (see Levitsky and Way, 2010). Authorities in Russia, for example, deprivatized valuable assets, such as gas and oil companies, owned by foreigners and business leaders supporting political opponents to ensure corporate ownership would cooperate with them. In reasserting control over the economy, authorities have become adept at using industry to further their national and geopolitical interests in the near and far abroad. At the same time, many authorities in the former Soviet Union have quashed internal opposition to ruling interests. The expansion of violent entrepreneurs into business and politics during 1990s has made it easy for members of ruling coalitions to find compromising material on challengers even if they themselves had connections to criminal groups as well.

Recent de-democratization in the former Soviet Union has the potential to compromise some real advances made in social science on the region. In Western Europe and North America, the study of post-Soviet societies has now became part of the mainstream of the academy as another site for social scientific inquiry. In the former Soviet Union, domestic social scientists conduct large-scale, empirical research projects using a variety of methods standards in social science. But, post-Soviet authorities have recently denounced some critical findings of social science research as designed by foreign interests to be biased against them. Emerging official suspicion of and barriers to conducting independent research projects could hurt cooperation between international and domestic social scientists and stall the progress already made.

Abstract

Following brief comments on the term and time frame, the article outlines the principle aspects and effects of the Revolution. In the foreground are the political constitution and system of government (parliamentary vs soviet government), the social upheaval (rise of the lower classes, new functionary elites), the disintegration of the empire, and the rise of national independence movements like the cultural revolutionary 'Iconoclasm'.

The term, Russian Revolution, is used ambiguously. It refers to varying events and time frames. Normally, it means the major upheaval of 1917 that replaced the tsarist empire with Bolshevik rule. In this case, the term can refer to either the demise of the monarchy in the so-called *February Revolution* (24 February/8 March NS to 2/15 March) or to the *overthrow of 25–26 October* (7–8 November) when the Bolsheviks seized power in the Petrograd Soviet of Workers' and Soldiers' Deputies. But 'Russian Revolution' is often extended to denote longer processes and obviously related sequences of events of the same type. In this case, the term encompasses the 1918–20 Civil War, which immediately followed the October Revolution as well as the subsequent early Soviet period up to the *Stalin Revolution* of 1929–30 or – the widest definition – the entire transformation of Russia from the turn of the century and so-called *First Revolution* of 1905–06 all the way down to the Stalin Era. Looking at it this way, the 'Russian Revolution' covers Russia's peculiar political and socioeconomic modernization crisis, which ended in the establishment of the Soviet Communist dictatorship (1900–30).

Substantive reasons and the question of research feasibility suggest narrowing this range of definitions somewhat. 'Russian Revolution' should be restricted to the convulsive transition from the Russian *ancien régime* to the Bolshevik form of government. The term properly denotes the two core events of the transfer of power: the overthrows of February and October and their consequences. However, there are valid reasons to include the Civil War because it was by nature the inevitable, belatedly waged war of revolution. Both time frames (1917 and 1917–21) lend themselves to differentiation of processes into *politics and power struggle*, *socioeconomic* change, and *cultural and nationalist* developments.

Political Constitution and System of Government

Political change in 1917 consisted of the succession from the monarchy to the 'emergency democracy' (D. Geyer), the Provisional Government (2/15 March to 26 October/8 November), to the soviet-based rule of the Bolsheviks with the 'Left Socialist Revolutionary Party' as a junior partner. Neither the direction of change nor the options in the year of revolution can be understood without a look at preceding developments. By the same token, the consolidation and transformation of the outcome cannot be explained without reference to the Civil War. The impetus for criticism of the autocracy definitely came from circles just outside the seat of power. Liberal forces in the aristocracy, the industrial–commercial upper class, which had developed ample political self-confidence, and the recently established academic intelligentsia rallied to the cause of constitutional restraint of the absolute monarch. But already during the grave state crisis of 1905–06 widely differing views were held on the extent of a say the parliament (Duma) should get in government. Following the restabilization of tsarist rule only moderate demands were still voiced by the groups that were allowed to operate legally. Nonetheless the 'revolution', a term, which cannot withstand any close scrutiny, clearly engendered a new political system and apparently a new distribution of power, although opinion is divided on the latter claim. Its legacy included a parliament, a party spectrum (albeit an incomplete one) and a politically outspoken press. Moreover, regional self-government (*zemstva*) had appeared alongside the central government and gained more and more powers. The First World War accelerated this shift. Ultimately the *zemstva* guaranteed the last remnants of public administration, which otherwise almost had ceased to function. Food supply had broken down, fuel was scarce, and the black market flourishing.

Only this background explains why a protest by workers' wives against hunger and cold swelled to a mass uprising, which toppled the monarchy. The last week of the 300 year Romanov rule began with an International Women's Day demonstration, which only differed from numerous past rallies in the number of participants. A repeat performance represented a new quality. In the next few days the movement escalated into a general strike of workers in the capital, and local military units joined the protest. The revolution, in the strict legal sense as a new edition of sovereignty, took place on 28 February when a Duma committee without authorization of the tsar appointed itself as the Provisional Committee for the Restoration of Public Order, thereby seizing power. At the same time the Workers' Soviet, which had convened the day before on the lines of the fall 1905 council, elected an analogous body. This established the *two principal political institutions*, which constituted the so-called *February Regime* ('dual power') of the following year. They represented two different social classes, requiring mediation of interests by the Provisional Government, first formed by the Liberals (embodied by the *Constitutional Democratic* Party), after 5/8 May together with the moderate wings of the *Socialist Revolutionary* and *Menshevik*

Social Democratic parties. The general correspondence between social affiliation and party orientation including institutional representation is indicative first of the marked polarization in the society and second of the absolutely crucial requisite for survival of the February order: building a bridge between the two fronts.

This became harder and harder to do from early summer on. Several factors contributed. With the government and the ruling parties it was a growing induration of personal animosities and of positions on issues. But a more serious aggravation was the result of omissions and a bad decision. The *Kerensky* Offensive of June/July, named after the premier, was a fatal error. It ended in a fiasco, which not only caused foreign policy damage. It also discredited the Provisional Government at home. Economic depression worsened simultaneously. Unemployment spread as more and more companies failed. Strikes and demonstrations proliferated, bringing the state to the brink of anarchy. The formation of new coalitions and two 'Reconciliation Congresses' (with different makeups) were unable to check the rapid erosion of authority of the February Regime.

This benefited the *Bolshevik* Social Democratic Party, which declared an irreconcilable struggle with the 'capitalist government' when their undisputed leader, V.I. Lenin, returned to Petrograd from Swiss exile on 3/16 April. They only had to channel the workers' and soldiers' misery and disenchantment over the failure of the new system. With all this grist for their mills, the Bolsheviks easily won great popularity. The spring splinter party was the strongest political force by the time the capital city councils were reelected in September. What had happened and was about to happen was clearly evidenced by the dramatic change of leadership in the Petrograd Workers Soviet. The Bolshevik Trotsky replaced the Menshevik Chkheidze as chairman.

The 'Red October' (R.V. Daniels) has produced much controversy. Soviet historiography, adhering to ideology, saw it as the investing of the first socialist state in the history of the world by the power of the masses. Others insisted on interpreting it as a military coup. There is no question that the seizure of power in the city garrisons from 22 October to 4 November was executed before everyone's eyes by the Bolshevik-dominated Military Revolution Committee in defense of the Soviet. It is also undisputed that the Bolsheviks were able to obtain the support of a majority of delegates to the Second All-Russian Congress of Soviets, which convened on 25 October. With this backing they managed to elect a presidium, more than half of whose members were their loyal supporters, while another third consisted of their Left Socialist Revolutionary sympathizers. To top it all off, the 'Right' Social Revolutionaries and the Mensheviks did them the favor of resigning their seats. Finally, the unchallenged occupation of strategic buildings and points in the city suggests that (unlike in Moscow a little later) there was no resistance worth mentioning. However, it is equally obvious that armed force was used against a legitimate government that had become unpopular but had been elected by parliament. The capture of the Winter Palace and the arrest of ministers pointedly attest to the nature of the overthrow. The maneuver accomplished by the Bolsheviks with the help of their Red Guard was 'technically' a military rebellion and politically a *coup d'état*. But it was only possible because it was undergirded by the majority of the Soviet deputies and the tolerance, if not the sympathy, of the urban lower classes, and locally stationed soldiers in particular. Thus, the 'art of insurrection' preached and wholeheartedly practiced by Lenin more or less boiled down to picking up the power that was lying in the street (N. Sukhanov).

The only question remaining was whether the Bolsheviks could maintain control. The wishes of the rebellious and potentially rebellious masses were quickly satisfied. Early on 26 October, the Soviet Congress passed a Peace Decree and a Land Decree. The intention of obtaining an immediate cease-fire secured the support of the soldiers for the overthrow. Distribution of large estates among village communes sanctioned transfers that had taken place much earlier and neutralized the peasantry. Overcoming the other parties and adherents of the *ancien régime* entailed a real struggle. It was inextricably tied to the independence movements of non-Russian nations and lasted until March 1921. Beginning in spring 1918 it escalated into the bloodiest war fought on Russian soil since the early seventeenth century. Actually, it started, still without recourse to weapons, right after the October coup. In the end the Bolsheviks maintained the upper hand so that they could begin the peaceful construction of 'their' state. However, at this juncture the fundamental decisions on its structure had already been made, and they were only superficially and temporarily amended, if at all, by the proclamation of the New Economic Policy.

The most important trend reflected Lenin's practical 'interpretation' of the slogan, 'All Power to the Soviets', as 'All Power to the Bolsheviks', which is what he had in mind in the first place. This usurpation was gradual. The cooperation between the Bolsheviks and the Left Socialist Revolutionaries in the October night session became a formal coalition in mid-November. Even this collaboration was based on the exclusion of not only the Liberals, but also the Mensheviks and 'Right' Socialist Revolutionaries. This confrontation manifested itself in the *alternative* between the *soviets* and the *Constituent Assembly*. When the latter was forcibly dispersed on 6/19 January 1918, it was not only the final curtain on the attempt to erect a democracy in posttsarist Russia. It also strained the common ground between the coalition partners. Though the Left Socialist Revolutionaries' Central Committee agreed to the dissolution, tensions within the bipartisan government grew. The collapse came after intense conflicts over the separate peace treaty of Brest-Litovsk in March. Now one-party rule and the fusion of party and state began in earnest. The system that lasted until 1991 was established.

Moreover, at least three other features of the new government and political system had their roots in the post-October clashes. First, the life-and-death struggle fostered the emergence of extraordinary organs and extreme centralization of decision making. Both measures were only partially rescinded. The most important institutional legacy was the Cheka, which was soon an army of its own, operating in the hinterland and authorized to administer martial law. As a secret police, the Cheka later became a synonym for totalitarian rule because it was empowered to execute arbitrary force beyond and above the law and was only subordinated to the top party leaders. A second fundamental decision was subjecting the economy to the control of the party and the government. Starting in

December 1917, the regime nationalized first the banks and big industry, then during the Civil War commerce and small business as well. Officially control was assumed by a pyramid of economic councils; *de facto*, however, since the unions had been forced to march in step, by members of the only legal party. In addition, an increasing intolerance of intraparty criticism reinforced the concentration of power and authority. The relative laxness, which the Civil War encouraged in 1919 yielded at the conclusion of hostilities to a 'prohibition of factions' (March 1921), which Stalin used as a decisive weapon in the power struggle for Lenin's succession. Finally, the Red Army was created in the fight for the spoils of the October Revolution. Even though its structure and personnel underwent several reshuffles, one birthmark was never effaced – its orientation on the regime and the party.

Social Upheaval

The revolutionary movement united political and social objectives from the start. It laid its claims in the name of the lower classes, which it always viewed as exploited. The Socialist Revolutionaries acted on behalf of all the 'enslaved', but primarily the peasants, while the Social Democrats marched in the name of the urban 'proletariat'. The Liberals, on the other hand, considered themselves to be 'class neutral'. But actually this camp had a social stratum of its own, ranging from the reform-oriented aristocracy and the intelligentsia to the commercial–industrial bourgeoisie. In the first revolution, these various tendencies underwent symbiosis. The nearly identical timing of the general strike in the capital and the peasants' storming of the agricultural estates in fall 1905 shocked the state to such an extent that it agreed to concessions to the democratic demands of the Liberals.

In February 1917 similar convergence took place, with one fundamental difference. Instead of the pincer attack of workers and peasants, an alliance of workers and garrisoned (not front line) soldiers led the assault. This time the *peasants* remained aloof. The agrarian revolution took place later, but more violently than ever before, *after* the collapse of the tsarist state and its rule by force in summer 1917. Later the rural population divorced itself from the urban revolutionary movement and went its own separate way until fall 1918. The core significance of the upheaval can be summed up with *one* result: the wildcat (i.e., spontaneous) redistribution of the property of the landed aristocracy. The peasants seized that which they had always believed to be their rightful possession. The predominant form of the operations was characteristic of the peasants' ties to tradition. Most villages acted collectively and allotted the land to commune members according to the dictates of custom to be used for a certain length of time. Ownership remained in the hands of the *obshchina*, and private property came into existence *de facto* only because hardly any redistribution occurred thereafter. Following this, their revolution, the peasants were sated. Events and problems beyond their village left them cold. Since the New Economic Policy legalized the reform, they could perceive themselves as the winners of the revolution despite the horrors of the Civil War. However, this redistribution wreaked havoc on the economy. It abolished the large cultivated holdings which yielded a large part of the farm produce sold elsewhere and reduced the average acreage to a level which hardly sufficed for efficient and stable production for the market. The outcome was a crisis-proneness that provided a convincing argument for a centrally planned economy.

The consequences of the February 1917 general strike of the Petrograd *workers* were more complicated. From the standpoint of the protagonists, the medium-term ramifications were negative. The rebels only managed to obtain their demands in the short run. Wages increased substantially, and working hours were reduced, even though the principal demand, a law stipulating an 8 h workday, was not achieved. Personal and social security were markedly improved. But the galloping inflation and unemployment following the economic collapse offset these benefits from early summer on. This setback made it possible for the syndical factory committee movement to extend the say in management it had gained in Petrograd in March to full control more than ever before. Its victory was hollow because the victors inherited the administration of the bankruptcy. To add insult to injury, the expectations it cherished after the October overthrow were completely dashed. If the Bolsheviks had a typical way of dealing with 'their' constituency, it was revealed in their relations with the factory committees. Before the overthrow they adopted the demands of the committees; after the Bolsheviks seized power, they also succeeded in gaining control of these organs. At the beginning of the year the 'anarchistic-decentralized' factory committees were muzzled by the unions, which themselves were on the way to becoming a 'transmission belt' (Lenin) of the party. All that remained was the disappointment over unkept promises, which triggered spreading strikes, the rebellion of Kronstadt sailors and intraparty criticism ('Workers' Opposition'). All this dissidence was suppressed by spring 1921, in many cases with extreme brutality.

Disintegration of the Empire and National Independence Movements

The liberal political and sociological views of the Russian Revolution have overlooked too much evidence that it was also a *national* movement. Incipient emancipation campaigns were exhibited in the first 'crisis of authority' in 1905–06. Social unrest in the Baltic Provinces and in Poland were particularly violent. There and in the Caucasus it expressed a desire for autonomy. The first authentically freely elected State Duma had several national factions and a total of about 45% non-Russian deputies. Following the 'prewar' and war period, which gave these movements an enormous boost, and the collapse of the tsarist empire, the national outbursts flared up as attempts to secede by force. Favored by the 'an-archy' in the literal sense created by the power vacuum, not only the 'old' nations like Poland and Finland and non-Slavic Baltic and Caucasian regions declared independence from the Petrograd central government. Nuclei of the old empire such as Ukraine joined the breakaway trend. It was not without cause that the June 1917 resolution of the Ukrainian *Rada* (council) declaring it would act as a formally independent body plunged the Provisional Government into an extremely severe crisis. The Bolsheviks supported this national emancipation only verbally

and for tactical reasons. Prior to their power seizure and during the Civil War in the peripheral areas of the empire, they espoused the doctrine that nation states had to reclaim their historical rights in the 'bourgeois phase' of the revolution. However, the stronger the *socialist* self-awareness of the new regime became, the more it again embraced the necessity for a unitary state. In fact, the Red Army acted from the beginning as an arm and an instrument of Great Russian centralism, which regained control of the old empire – with the exception of Finland, Poland, and the new Baltic republics – by the end of the Civil War. If one looks very closely, this resulted inevitably from the political foundations of the new state. Since only one political force was legal, it had to be centralist. Therefore the Soviet Union established in 1922 was only formally a federal system. In truth it was an anachronistic multinational empire in a postwar world organized into nation states and dominated by nationalisms.

Iconoclasm

Last but not least, scholars have recently remembered to highlight the extremely radical cultural upheaval the Russian Revolution entailed. In the first place, it had a salient 'ideocratic' dimension. The Leninist version of radical Marxism was an ideology with the political power to stake a claim to shaping all sectors of public life, ultimately also of private life of the people under its sway, from work to education, according to fundamentally new, theoretically preconceived principles. The October overthrow ushered in the first regime in modern history to make a specified interpretation of world history and destiny, including a programmatic, militant atheism, obligatory. The radical Bolshevik Revolution unleashed an unprecedented outburst of all kinds of 'antiestablishment' movements, almost entirely borrowed from Western European modernism. They were of a sociopolitical (women's liberation), intellectual aesthetic (abstract art, '*Proletkult*') and pedagogical nature (polytechnic education, public health). Even though this experimental exuberance was a source of aggravation to the party and government leadership and its wings were gradually clipped after the conclusion of the Civil War, it survived in isolated pockets until definitively forced into submission by Stalin. In the aesthetic sector, the 'revolutionary culture' is universally credited with significant achievements.

Abstract

There is no scholarly consensus regarding the meaning of the term 'sacrifice,' and the term is best regarded as a polythetic category that includes heterogeneous modes of behavior motivated by human intentions of variable kinds. These include commemoration, initiation, expiation, propitiation, establishing a covenant, or affecting a transition in social status. In more elaborate forms than straightforward ritualistic gift-giving, sacrifice typically involves a set of four terms: (1) sacrificer, the executor of the ritual; (2) sacrifier, the beneficiary of the sacrifice; (3) the object sacrificed; (4) the deity who receives the sacrifice. Various 'approaches' to the study of sacrifice have been proposed, and among the most useful are: (1) sacrifice as gift; (2) sacrifice as communion; (3) sacrifice as causality; (4) sacrifice as symbol system; and (5) sacrifice as catharsis. Sacrificial rituals have an ancient pedigree that extends into prehistory. So pervasive is it in time and space that a case could be made that sacrificial behavior is one of the natural dispositions common to the species *Homo sapiens*.

There is no scholarly consensus regarding the meaning of the term 'sacrifice.' In its widest usage the term, which derives from the Latin *sacrificium*, is applied to virtually any form of gift-giving to a deity. A more restricted application limits its use to situations in which the gift is mutilated or destroyed. An even more restrictive usage is suggested by the Oxford English Dictionary (Simpson and Weiner, 1989/1933), whose primary definition is 'the slaughter of an animal (often including the subsequent consumption of it by fire) as an offering to God or a deity.'

The term sacrifice is, therefore, best regarded as a polythetic category which includes heterogeneous modes of behavior motivated by intentions of variable kinds. These include commemoration, initiation, expiation, propitiation, establishing a covenant, or affecting a transition in social status. Regarding sacrifice not as constituting a class of phenomena having a fixed set of features in common but as a multivocal term applying to phenomena that merely have 'family resemblances' in common has the advantage of mitigating somewhat the Euro-centric bias inherent in the work of many of the most influential thinkers on the subject, among them Robertson Smith (1894/1927), Hubert and Mauss (1898), and Durkheim (1912). 'The Sacrifice' for this generation of scholars was the central feature of religion, a Judaic Christian bias still evident as late as 1956, the year in which E. E. Evans-Pritchard published his classic, *Nuer Religion*. Tellingly, Evans-Pritchard did not identify any word in the Nuer language that unambiguously corresponded to the English 'sacrifice.' This lack of correspondence appears widespread. Benveniste (1969: p. 223), for example, could discover no common word for sacrifice in the Indo-European languages.

The Terminology of Sacrifice

In more elaborate forms than straightforward ritualized gift-giving, sacrifice typically involves a set of four terms. First, there is the sacrificer, the executor of the ritual. Second, there is the sacrifier, the beneficiary of the sacrifice. This may be the executor of the ritual, individual members of the community, or the community *in toto*. Third, there is the object sacrificed. Although this gift may be anything, ethnographic descriptions usually emphasize the bloody sacrifice of a living being, in which case blood typically is described as connoting such ideas as fertility, renewal, replenishment, vitality, life force, and empowerment.

Access by the sacrifier to these desirables is acquired when this substance is shed in ritual by the act of forcing life out of the victim. Substitution, or the use of a surrogate in cases when the offering is that of a human being, is a common occurrence, so frequently resorted to that some writers, including two who have made important contributions to the topic – de Heusch (1986) and Bloch (1992: p. 32) – consider substitution to be a key feature of sacrificial rituals. Fourth, there is the deity to whom the sacrifice is made.

Approaches to the Sacrifice

A number of distinguished thinkers have advanced what might be termed 'approaches' to the study of sacrifice, which afford insightful, though overlapping, perspectives. Among the most useful are the following five.

Sacrifice as Gift

For Tylor (1871/1913), following Plato, the sacrifice was a gift made to an anthropomorphic divinity, much as a gift might be given to a chief, whose acceptance made the deity indebted to humanity. This approach was popular with nineteenth century scholars, who attributed to the act of sacrificing such motives as expiating sins, obtaining benefits, nourishing the deity, and

establishing good relations between human beings and spirits. This theory lays stress on the beliefs of the givers rather than on the ritual performance itself, which in this interpretation is relegated to logically subservient status. This approach is at the same time too broad and too narrow. It is overly broad in that these motives undoubtedly are widespread in many rituals of sacrifice all over the world, yet excessively narrow since sacrificial rituals are employed to do much more than simply offer gifts.

Sacrifice as Communion

Robertson Smith (1894/1927), in contrast to Tylor, granted priority to ritual, a ranking modern ethnographic fieldwork tends to validate. Robertson Smith's main point was that early Semitic sacrifice, and by implication sacrifice among nonliterate peoples, was a feast human beings communally shared with their deity. He understood the immolated victim to be the clan totem, an animal that shared in the blood of its human kin. It was also the clan ancestor, which was the clan deity, so in consuming their animal victim members of the community were eating their deity. This act of consumption conferred spiritual power.

Later research in the field undermined much of Robertson Smith's argument, but unquestionably the sacrifice does offer a means by which human beings may conjoin with their deity and establish a relationship, and here Robertson Smith did have insight. He strongly influenced Hubert and Mauss, whose *Essai sur la nature et la fonction du sacrifice*, which appeared in 1898, remains the basic work on the topic. Like all the studies of the time, it depended entirely upon secondary and tertiary sources rather than original ethnography, and the authors further restricted their sources to Sanskrit and Hebrew texts. To them the most significant feature about the sacrificial feast was that it provided the mechanism by which communion, in the sense of communication between human beings and deity, could be brought about. It was made possible by the fact that the victim represented both sacrifier and divinity, thus breaking down the barrier between the sacred and the profane (a moral contrast that played a major role in their approach). Yet, although the sacrifical act conjoined the sacred and profane, it could also disjoin them since while there were sacrifices that brought the spirit into the human world and made the profane sacred, there were also sacrifices that removed the spirit from the human world and made what had become sacred, profane. The former Hubert and Mauss called rituals of 'sacralization;' the latter, rituals of 'desacralization.' Even though Evans-Pritchard – who was very much influenced by their ideas – found this distinction among the Nuer (1956: pp. 197–230), it is by no means as universal as they supposed.

Hubert and Mauss were intrigued by those sacrifices in which it is the deity that offers his life for the benefit of his worshippers. As they saw it, the exemplary sacrifice was that of a god, who, through unqualified self-abnegation, offers himself to humankind, in this way bestowing life on lesser beings. The most celebrated example of this is the central ritual of the Catholic religion, the Mass, where Christ's sacrifice on the Cross is re-enacted. In a sacrifice of this nature the relationship between the deity and worshippers raises the question of relative status. From Hubert and Mauss' perspective the relationship is one of grave imbalance since the deity gives more than it gets. This may appear so, but Valeri (1985: pp. 66–67) has advanced a sophisticated argument designed to prove that sacrifice actually creates a bond of 'mutual' indebtedness between the human and the divine, which makes each party dependent upon the other. This proposition may not be true universally, but support for Valeri's argument comes from the bear sacrifices carried out by the Ainu of Japan. In these, the immolation of bears brings fertility to the community and nurture to the spirits (Irimoto, 1996).

Durkheim's (1912) distinctive contribution, which otherwise relied heavily upon Hubert and Mauss, and Robertson Smith, was to promote the importance of sacrificial activities in bringing about social cohesion and the values that contribute to this cohesion. In Timor, a South Pacific island, a ritual is performed in which a local king is figuratively slain by members of two ethnically different communities (Hicks, 1996). The king, who comes from one of these groups, symbolizes their unity as a single social entity at the same time that he symbolizes their local god. In addition, by periodically immolating their king the two groups regenerate their notions of 'society' and 'god' as epistemological categories.

Sacrifice as Causality

For Hocart (1970: p. 217) the most compelling reason for performing collective rituals was the 'communal pursuit of fertility.' A sacrifice is offered to the gods in order that life and the fertility that engenders and sustains it are acquired by the community, a view that focuses upon sacrifice as a practical device to affect empirical transformation. Catholic rituals before the Reformation were thought of in this way; afterwards they were reinterpreted as a symbolic process (Muir, 1997). For Catholics the Mass materially transformed the bread into Christ's body; for Protestants the bread merely represented Christ's sacrifice.

Sacrifice as Symbol System

More contemporary scholars, such as Valeri (1985), have emphasized the symbolic character of sacrificial behavior, analyzing its structure and isolating its motifs within the wider context of a society's ideology. In this approach, the array of symbols isolated is then apprehended as a semantic system whose meaning requires decoding. Valeri's interpretation of Hawaiian sacrifice, for example, requires that sacrificial rituals be understood as a symbolic action 'that effects transformations of the relationships of sacrifier, god, and group by representing them in public' (1985: pp. 70–71). Although vulnerable to the criticism that it relies too heavily on the subjective bias of the analyst, this approach has the advantage of enabling sacrificial practices to be understood within a wider social context, at the same time as it allows an analysis of sacrifice to open up a distinctive perspective on society.

Sacrifice as Catharsis

Another approach to sacrifice is to focus on violence. Girard (1972), most notably, has suggested that sacrifice offers

a socially controlled, and therefore, socially acceptable, outlet for the aggressive urges of human beings. The typical manner by which this is accomplished is to use a sacrificial victim as a scapegoat. A more recent scholar who has stressed the importance of violence in sacrifice is Bloch (1992), but his approach differs from that of Girard in that for Bloch sacrifice requires violence because human beings need 'to create the transcendental in religion and politics,' and that this is attainable through violence done to the victim (Bloch, 1992: p. 7). One difficulty with this approach is that behavior that one might arguably class as sacrificial may involve no violence at all.

Origins of Sacrifice

Sacrificial rituals have an extensive pedigree. One of the earliest for which a reasonably detailed record is available dates from about 3000 years ago. The Vedic Aryans held sacrifice to be their central religious activity (Flood, 1996: pp. 40–41), and it consisted of putting milk, grains of rice and barley, and domesticated animals into a sacred fire that would transport the offerings to supernatural entities. As the Agnicayana, this ritual is still carried out in Kerala, southwest India.

Evidence for sacrificial behavior extends further back than Vedic times, to the civilizations of Sumer 5000 years ago and China 4000 years ago, and its presence seems accounted for even further in the past. This long history, taken with the widespread practice of sacrifice all over the world, suggests that a case could be made that sacrificial behavior is one of the natural dispositions common to the species *Homo sapiens*. As Needham (1985: p. 177) has averred for ritual in general, it may be that sacrifice, 'Considered in its most characteristic features … is a kind of activity – like speech or dancing – that man as a ceremonial animal happens naturally to perform.'

Abstract

The economics of safety examines workplace injuries. In neoclassical theory, employers pay a risk premium for hazardous work and invest in safety to reduce the premium. 'Modified neoclassical theory' argues that limited types of government regulation improve the operation of the labor market. The 'old institutional economists' emphasize the unequal bargaining power of individual workers. One strain of 'new institutional economics' asserts that, when transaction costs are significant, changing the legal rules about liability can affect the allocation of resources. The government mandate theory argues that government standards improve safety. Evidence supporting the various theories is evaluated.

Introduction

The economics of safety is concerned with the causes and prevention of accidents resulting in economic losses. The primary focus is on accidents causing workplace injuries and diseases. The topic is examined using several variants of economic theory. In 'pure' neoclassical economics, employers pay a risk premium to workers for hazardous jobs and invest in safety to reduce the premiums. There is evidence of risk premiums, but the amount may not fully compensate workers for their risks. Modified neoclassical economics recognizes that some types of government intervention are appropriate in order to overcome the attributes of the labor market that do not correspond to the assumptions of pure neoclassical economics. Old institutional economics (OIE) emphasize the unequal bargaining power of individual workers as another limitation of the labor market as envisioned by pure neoclassical economics. Workers' compensation is a no-fault program providing benefits to injured workers that is endorsed by critics of neoclassical economics because premiums are experienced rated – they vary among industries and firms based on prior benefit payments – which in theory provides economic incentives to employers to improve safety. However, recent studies have cast doubt on whether experience rating improves workplace safety. Consistent with OIE, evidence suggests that collective action by workers improves workplace safety.

New institutional economics (NIE) includes devotees of the Coase theory and transaction cost economics, who argue that when transactions costs (including the expenses of drafting and enforcing agreements) are high, changes in liability rules can affect the allocation of resources, including those devoted to safety. Evidence supporting this theory includes the improvement in workplace safety when the workers' compensation program replaced tort remedies in many states in the early twentieth century.

Law and economics (L&E) theory draws on neoclassical economics and transaction cost economics in the examination of legal institutions. One application considers the stimulus of tort law to safety: while theory postulates a positive effect of tort suits on safety, the evidence suggests these suits do not provide much assistance in deterring accidents.

Government mandate theory argues that government promulgation and enforcement of standards will improve workplace safety and health. However, several studies suggest that safety standards in the United States have done little to improve workplace safety and that, rather than overcoming deficiencies of an unregulated labor market, have often been excessively stringent.

'Pure' Neoclassical Economics

The neoclassical theory of work injuries is examined in Thomason and Burton (1993). Workplace accidents are undesirable by-products of processes that produce goods for consumption (Oi, 1974). Several assumptions are used in the neoclassical analysis of these processes. Employers and workers have an ongoing relationship. Employers maximize profits. Workers maximize utility, not just pecuniary income. Workers at the margin are mobile and possess accurate information concerning the risks and consequences of work injuries. One implication of these assumptions is that employers pay higher wages for hazardous work than for nonhazardous work. On the assumption that accident insurance is not provided by employers or the government, the equilibrium wage for the hazardous work will include a risk premium equal to the expected costs of the injuries, which includes lost wages, medical care, and the disutility caused by the injury. If workers are risk averse, the premium will also include a payment for the uncertainty about who will be injured.

The employer has an incentive to invest in safety in order to reduce accidents and thus the risk premium. The firm will make safety investments until the marginal expenditure on safety is equal to the marginal reduction in the risk premium. Since there is a rising marginal cost to investments in safety, equilibrium will occur with a positive value for the risk premium, which means that in equilibrium there will be some work injuries.

Evidence Consistent with the Neoclassical Model

There is an extensive literature on compensating wage differentials for the risks of workplace death and injury. Ehrenberg and Smith (2012) report that recent estimates suggest wages are about 1.0% higher for workers facing a fatality risk twice the average risk of job fatalities (about 1 per 25 000 workers

per year). The evidence on risk premiums can be used to estimate a value of statistical life (VSL), which represents evidence from the market about the willingness of people to pay for a reduction in the risk that they will be killed. Shapiro (2009) provides an example: if the average annual wage premium for the risk of work-related death is $400 and the annual fatality risk is 1 out of 10 000 workers, then the VSL is $4.0 million ($400 divided by 0.000 1).

Viscusi and Aldy (2003) reviewed more than 60 studies of mortality risk premiums from 10 countries and approximately 40 studies estimating injury risk premiums. Estimates using US labor market data typically show a VSL in the range of $4–$9 million (in 2000 dollars). Their review included 20 studies of non-US labor markets, including those of the United Kingdom (with significantly higher VSLs than in the United States), Canada (with the most VSL estimates in the range of US$3–US$6 million), and several developing countries, including India and Korea, in which VSL estimates are generally much lower than in developed countries. Across countries, the VSL generally increased with levels of income (income elasticities of about 0.5–0.6). Other general results include higher VSLs for union workers and decreasing VSLs for older workers. Leigh and Ruser (2003) found that compensating wage differentials for fatal and nonfatal injury risks vary according to gender and race.

Qualifications Concerning the Neoclassical Theory

The model that postulates workplace safety results from risk premiums, which provide financial incentives to employers to invest in safety, has been challenged. Some critics assert that risk premiums are inadequate because workers lack sufficient information about the risks of work injuries and/or have limited mobility to move to less hazardous jobs. However, Viscusi (1993) refers to a sizable literature in psychology and economics documenting that individuals tend to overestimate low probability events, such as workplace injuries, which could result in inappropriately large risk premiums. Ehrenberg and Smith (2012) conclude that workers have enough knowledge to form judgments about the relative risks of various jobs 'with some accuracy.' Both Ehrenberg and Smith (2012) and Viscusi (1993) argue there is sufficient worker mobility to generate risk premiums. Another challenger to the neoclassical model is Rose-Ackerman (1992), who argues that the labor market does not generate proper risk premiums because certain costs resulting from work injuries are not borne by workers but are externalized.

The empirical evidence on risk premiums has also been challenged or qualified. Ehrenberg and Smith (2012), for example, conclude that the studies of compensating wage differentials for the risks of injury or death on the job "generally, but not always, support the prediction that wages will be higher whenever risks on the job are higher." Viscusi (1993) concludes: "The wage-risk relationship is not as robust as is, for example, the effect of education on wages."

The most telling attack on the compensating wage differential evidence is by Dorman and Hagstrom (1998), who argue that most studies have been specified improperly. They argue that, after controlling for industry-level factors, the only evidence for positive compensating wage differential pertains to unionized workers. For nonunion workers, they argue that properly specified regressions suggest workers in dangerous jobs are likely to be paid less than equivalent workers in safer jobs.

The Dorman and Hagstrom attack on the previously generally accepted view – dangerous work results in risks premiums for most workers – was challenged by Viscusi and Aldy (2003). However, even if every empirical study finds risk premiums for workplace fatalities and injuries, the evidence would not conclusively validate the neoclassical economics approach. Ehrenberg (1988) provides the necessary qualification: if there are any market imperfections (such as lack of information or mobility), the "mere existence of *some* wage differential does *not* imply that it is a fully compensating one." And if the risk premium is not fully compensating (or is more than fully compensating), then inter alia, the market does not provide the proper incentive to employers to invest in safety.

Modified Neoclassical Economics and the Old Institutional Economics

Some economists rely on a 'modified' version of neoclassical economics theory that recognizes some types of government intervention are appropriate in order to overcome the attributes of the labor market that do not correspond to the assumptions of pure neoclassical economics. These attributes include the lack of sufficient knowledge and mobility by employees, and the possible lack of sufficient knowledge or motivation of employers about the relationship between expenditures on safety and the reduction in risk premiums. Proponents of the OIE would agree with these critiques of lack of knowledge and mobility, and would also emphasize factors such as the unequal bargaining power of individual workers as another limitation of the labor market as envisioned by neoclassical economists.

An example of government promulgation of information in order to overcome the lack of knowledge in the labor market is the Occupational Safety and Health Act (OSHAct) Hazard Communication standard, which requires labeling of hazardous substances and notification to workers and customers and which is estimated to save 200 lives per year (Viscusi, 1996). (Other aspects of the OSHAct are discussed below.)

Workers' Compensation

Workers' compensation programs represent another type of government intervention in the labor market in order to prevent workplace injuries and diseases, as well as to improve compensation for injured workers. Until late in the nineteenth century, the principal approaches used to achieve the goals of prevention and compensation were reliance on the risk premiums generated in the labor market and on negligence (tort) suits by injured workers against their employers (discussed below). Because of the dissatisfaction with these approaches, many countries enacted workers' compensation programs, beginning with Germany in 1884. Workers' compensation programs are a form of social insurance

providing cash benefits and medical care to disabled workers on a no-fault basis.

The enactment of workers' compensation programs result in moral hazard, which Harrington and Niehaus (1998) define as "the effect of insurance on the insured's incentives to reduce expected losses." Three types of moral hazard for workers resulting from the introduction of a workers' compensation program or from increases in workers' compensation benefits have been identified (Guo and Burton, 2010; Butler et al., 2013): (1) the true injury effect – workers may be less concerned about job safety and more willing to accept risk, which results in an increase in injury frequency and injury severity; (2) the reporting effect – workers will be encouraged to submit more claims for losses they otherwise would not have bothered to report; and (3) the duration effect – workers will extend the period for which they claim benefits.

Workers' compensation programs rely on several strategies to reduce moral hazard for workers, including (1) deductibles – workers do not receive benefits in the initial period after the workplace injuries occur because of waiting periods; (2) coinsurance – benefits only replace a portion of lost wages (generally 66 2/3% of wages in US state programs); (3) limits on eligibility for benefits – benefits are limited to those workers who meet legal tests included in workers' compensation statutes; and (4) limits on duration of benefits – some programs limit the duration of benefits, especially for long-term disabilities.

Moral hazard for employers also results from the introduction of a workers' compensation program or from increases in workers' compensation benefits, with the nature of the moral hazard depending on the method used to finance the program. Some workers' compensation programs are financed by premiums (or assessments) that are uniform for all employers. In contrast, the workers' compensation programs in the United States and to some degree in other countries, including Canada, France, and Germany, are financed by experience-rated premiums. The US variant of experience rating has two levels: industry-level experience rating, which largely bases the insurance rate for each industry on prior benefits in the industry, and firm-level experience rating, which determines the premium for each firm above a minimum size by comparing the firm's prior benefit payments to those of other firms in the industry. Analysts have identified three types of moral hazard for workers' compensation programs that relay on experience rating as opposed to programs financed by premiums that do not vary among employers (Guo and Burton, 2010; Butler et al., 2013): (1) the safety effect – employers will have more incentive to keep the workplace safe; (2) the underreporting or monitoring effect – employers will have more incentive to deny claims, which may be fraudulent, questionable, or legitimate; and (3) the rehabilitation or return-to-work effect – employers will have more incentive to adopt claims management practices that reduce the duration of benefit payments.

Two studies of US workers' compensation programs examined whether the moral hazard (or incentive) effects for workers or the incentive effects for employers dominate. Bronchetti and McInerney (2012) used a national data set on individuals in the United States and found that higher benefits resulted in fewer workers' compensation claims (the benefits–claims elasticities were less than 1.0). Guo and Burton (2010) examined the determinants of interstate differences in the Bureau of Labor Statistics (BLS) injury rate for two periods (1975–89 and 1990–99). The coefficients on expected benefits were statistically insignificant in both periods. The authors indicated that "One interpretation of these results is that true injury effect is offset by the safety effect." Guo and Burton also examined the determinants of interstate differences in workers' compensation cash benefits per 100 000 workers. The authors found that "the benefit elasticity (the association between expected benefits and actual benefit payments) was significantly less than 1.0 in both our study periods (1975–89 and 1990–99)." One interpretation of this result is that the monitoring and rehabilitation effects for employers were stronger than the reporting and duration effects for workers.

The Effects of Experience Rating according to Different Economic Theories

Experience rating has received considerable attention in recent decades. In the neoclassical economics model, the introduction of workers' compensation with experience rating should make no difference in the safety incentives for employers compared to the incentives provided by the labor market without workers' compensation. Under assumptions explicated by Burton and Chelius (1997), such as perfect experience rating, risk neutrality by workers, and actuarially fair workers' compensation premiums, the risk premium portion of the wage paid by the employer will be reduced by an amount exactly equal to the amount of the workers' compensation premium. Also, under these assumptions, the employer has the same economic incentives to invest in safety both before and after the introduction of the workers' compensation program. Under an alternative variant of the pure neoclassical economics approach, in which the assumption of perfect experience rating is dropped, the introduction of workers' compensation will result in reduced incentives for employers to reduce accidents.

In contrast, the OIE approach argues that the introduction of workers' compensation with experience rating should improve safety because the limitations of knowledge and mobility and the unequal bargaining power for employees mean that the risk premiums generated in the labor market are inadequate to provide employers the safety incentives postulated by the pure neoclassical economics approach. Commons (1934), a leading figure in the OIE approach, claimed that unemployment is the leading cause of labor market problems, including injuries and fatalities, because slack labor markets undercut the mechanism that generates compensating wage differentials. Commons asserted that experience rating provides employers economic incentives to get the 'safety spirit' that would otherwise be lacking. Many modified neoclassical economists also accept the idea that experience rating should help improve safety by providing stronger incentives to employers to avoid accidents, although they place less emphasis on the role of unemployment in undercutting compensating wage differentials and more emphasis on the failure of employers to recognize the cost savings possible from improved safety without the clear signals provided by experience-rated premiums.

Evidence on the Effects of Experience Rating

A number of studies of experience rating provide evidence that should help assess the virtues of the various economic theories. Almost without exception, the studies find that experience rating reduces the number of workers' compensation claims, which supports the argument that 'pure' neoclassical economics does not provide a sufficient explanation of the operation of the labor market. What is unclear, however, is whether the reduction in claims is a result of the safety effect – with fewer actual injuries – or is due to the monitoring effect – with employers denying more claims. The evidence on this issue is inconclusive. The survey of experience-rating studies by Boden (1995) concluded that "research on the safety impacts has not provided a clear answer to whether workers' compensation improves workplace safety." In contrast, Thomason (2005) asserted that most (11 of 14) studies he surveyed found that experience rating improves safety and health and concluded: "Taken as a whole, the evidence is quite compelling: experience rating works." A markedly different conclusion was reached by Mansfield et al. (2012), who concluded that:

> Although experience rating is intended to stimulate safer workplaces, a growing body of literature reveals that it has not achieved that effect . . . The absence of a safety effect may arise because employers focus on managing reported claims rather than prevention.

Mansfield et al. (2012) is contained in a collection of articles that provide largely negative assessments of experience rating. For example, Tompa et al. (2012) conclude their study of Ontario "suggests that experience rating provides an incentive for secondary prevention, but less so for primary prevention." There are also largely skeptical assessments of experience rating in Australia (Clayton, 2012; Purse, 2012) and in New Zealand (Armstrong and Bunn, 2012). The only 'good news' for experience rating was provided by Seabury et al. (2012), who found that workers injured at self-insuring employers (who are perfectly experience rated) have significantly improved return-to-work experience for up to 5 years after the date of injury.

The recent evidence that experience rating does not improve safety is inconsistent with the positive impact on safety postulated by the OIE approach and is also contrary to the views of some proponents of modified neoclassical economics. Additional studies of experience rating can be anticipated, as can disagreements about the wisdom of relying on this approach to promoting safety, in part because of recent studies demonstrating that many workers with disabilities caused by work do not receive workers' compensation benefits (Spieler and Burton, 2012).

Collective Action

While some modified neoclassical economists and the OIE largely agree on the desirability of several prevention approaches, such as the use of experience rating in workers' compensation, the OIE endorsed another approach that many modified neoclassical economists would not support, namely, the use of collective bargaining and other policies that empower workers. Collective bargaining agreements can minimize unsafe activities or at least explicitly require employers to pay a wage premium for unsafe work. Many agreements also establish safety committees that assume responsibility for certain activities, such as participation in inspections conducted by government officials. If workers are injured, unions can help them obtain workers' compensation benefits, thereby increasing the financial incentives for employers to improve workplace safety.

The beneficial effects predicted by the OIE approach for these collective efforts appear to be achieved. Several studies, including Weil (1999) concluded that Occupational Safety and Health Administration (OSHA) enforcement activity was greater in unionized firms than in nonunionized firms. Moore and Viscusi (1990) and other researchers found that unionized workers receive larger compensating wage differentials for job risks than unorganized workers. Hirsch et al. (1997) found that "unionized workers were substantially more likely to receive workers' compensation benefits than were similar nonunion workers."

There are also safety committees in some jurisdictions that are utilized in nonunionized firms. Burton and Chelius (1997) reviewed several studies involving such committees in the United States and Canada, and found limited empirical support for their beneficial effects. Reilly et al. (1995) provided a more positive assessment for their accomplishments in the United Kingdom. These studies provide some additional support for the beneficial role of collective action postulated by the OIE.

The New Institutional Economics

NIE authors generally argue that market forces encourage efficient forms of economic organization without government assistance and that opportunities for efficiency-improving public interventions are rare. This section considers only the Coase theory/transaction costs economics strain of NIE.

The Coase Theory and Transaction Costs Economics

In the absence of costs involved in carrying out market transactions, changing the legal rules about who is liable for damages resulting from an accident will not affect decisions involving expenditures of resources that increase the combined wealth of the parties. The classic example offered by Coase (1988) involves the case of straying cattle that can destroy crops growing on neighboring land. The parties will negotiate the best solution to the size of the herd, the construction of a fence, and the amount of crop loss due to the cattle whether or not the cattle rancher is assigned liability for the crop damages.

Coase recognized that the assumption that there were no costs involved in carrying out transactions was 'very unrealistic.' According to Coase (1988):

> In order to carry out a market transaction, it is necessary to discover who it is that one wishes to deal with … and on what terms, to conduct negotiations …, to draw up the contract, to undertake the inspection needed to make sure that the terms of the contract are being observed, and so on. These operations are often … sufficiently costly … to prevent many transactions that would be carried out in a world in which the pricing system worked without cost.

The goal of transactions costs economics is to examine these costs and to determine their effect on the operation of the economy. As scholars of transaction costs have demonstrated, when transactions costs are significant, changing the legal rules about initial liability can affect the allocation of resources.

Evidence Concerning Changes in Liability Rules

Workplace safety regulation provides a good example of a change in liability rules, since in a relatively short period (1910–20), most US states replaced tort suits (the employer was only responsible for damages if negligent and employers had extraordinary defenses even if negligent) with employer liability acts (the employer was required to be negligent but some or all of the extraordinary defenses were abrogated), which in turn were replaced with workers' compensation (the employer is required to provide benefits under a no-fault rule) as the basic remedy for workplace injuries. Fishback (1998) and Butler and Worrall (2008) provide excellent reviews of the empirical studies of these changes in liability rules, which are summarized in Burton (2009).

Studies differ on whether the changes in liability rules increased or decreased workplace accidents, depending on the workers' occupation and industry. The overall conclusion of Butler and Worrall (2008) was that "those who argue that the tort system generated better safety incentives than workers' compensation are wrong." This conclusion suggests that high transaction costs associated with the determination of fault in negligence suits were an obstacle to achieving the proper incentives to workplace safety, and that the institutional features of workers' compensation, including the no-fault principle, provided a relatively more efficient approach to the prevention of work injuries than tort suits for most workers. The transaction economics component of the NIE theory thus appears to provide a useful supplement to neoclassical economics, since institutional features, such as liability rules, can have a major impact on the economic incentives for accident prevention.

Law and Economics

L&E theory draws on neoclassical economics and transaction cost economics, but is distinctive in the extent to which it examines legal institutions and legal problems. This section examines the tort law branch of L&E theory, while the next section examines the employment law branch.

Theoretical Stimulus of Tort Law to Safety

Tort law typically is used when one party harms another party, and the parties do not have an ongoing relationship. However, even though workers and employers have a continuing relationship, tort suits were generally used as a remedy for workplace accidents in the United States until workers' compensation programs were established. When negligence is the legal standard used for tort suits, if the employer has not taken proper measures to prevent accidents and thus is at fault, the employer will be liable for all of the consequences of the injury. The standard for the proper prevention measure was developed by Judge Learned Hand and restated by Posner (1972) as:

> The judge (or jury) should attempt to measure three things in ascertaining negligence: the magnitude of the loss if an accident occurs; the probability of the accident's occurring; and the burden (cost) of taking precautions to prevent it. If the product of the first two terms, the expected benefits, exceeds the burden of precautions, the failure to take those precautions is negligence.

Posner argued that proper application of this standard would result in economically efficient incentives to avoid accidents. Burton (2009) examines some qualifications to this conclusion.

Evidence on the Tort Law Stimulus to Safety

Two types of empirical evidence suggest that skepticism is warranted about the stimulus to workplace safety from tort suits. First, tort suits were used as the remedy for workplace injuries in the late 1800s and early 1900s. As previously discussed, most studies find that replacement of the negligence remedy with workers' compensation led to a general reduction in workplace fatalities.

Second, in other areas of tort law, there is a major controversy among legal scholars about whether the theoretical incentives for safety resulting from tort suits actually work. One school of thought is exemplified by Landes and Posner (1987), who state that "although there has been little systematic study of the deterrent effect of tort law, what empirical evidence there is indicates that tort law … deters." An opposing view of the deterrent effects of tort law is provided by Priest (1991), who finds almost no relationship between actual liability payouts and the accident rate for general aviation and states that "this relationship between liability payouts and accidents appears typical of other areas of modern tort law as well, such as medical malpractice and product liability.'

A study of tort law by Schwartz (1994) distinguished a strong form of deterrence (as postulated by Landes and Posner) from a moderate form of deterrence, in which "tort law provides a significant amount of deterrence, yet considerably less that the economists' formulae tend to predict." Schwartz surveyed a variety of areas where tort law is used, including motorist liability, medical malpractice, and product liability, and concluded that the evidence undermines the strong form of deterrence but provides adequate support for the moderate form of deterrence. Dewees et al. (1996), after reviewing the evidence from several fields involving personal injury, including accidents involving automobiles, medical practice, and products, concluded that "the tort system performs unevenly in deterring the causes of personal injury, so its scope should be restricted to situations where its effect seems likely to justify its high cost." They recommended expanding the no-fault approach exemplified by workers' compensation to the motor vehicle and medical malpractice fields.

Burton and Chelius (1997) concluded and Burton (2009) affirmed that based on both the historical experience of the impact of tort suits on workplace safety and the current controversy over the deterrence effect in other areas of tort law, "the law and economics theory concerning tort law does not

provide much assistance in designing an optimal policy for workplace safety and health."

Government Mandate Theory vs Law and Economics Theory

The Government Mandate Theory

The government mandate theory argues that the government promulgation of health and safety standards and enforcement of the standards by inspections and fines will improve workplace safety and health. This is basically a legal theory, although many of the supporting arguments involve reinterpretation or rejection of studies conducted by economists. For example, proponents of the theory object to the evidence on compensating wage differentials and object in principle to economists' reliance on cost-benefit analysis. Supporters of the theory, such as McGarity and Shapiro (1996), also provide a positive case why OSHA is necessary:

> OSHA's capacity to write safety and health regulations is not bounded by any individual worker's limited financial resources. Likewise, OSHA's capacity to stimulate an employer to action does not depend upon the employees' knowledge of occupation risks or bargaining power.

The government mandate theory would not be endorsed by many economists, including the OIE. Commons and Andrews (1936), for example, criticized at length the punitive approaches that used factory inspectors in the form of policemen, since this turned employers into adversaries with the law. The minimum standards supported by the OIE were those developed by a tripartite commission, involving employers, employees, and the public, rather than standards promulgated by the government. While the OIE theory is, thus, unsympathetic to the government mandate theory, the sharpest attack is derived from the L&E theory.

The L&E Theory Concerning Government Regulations

L&E scholars make a distinction between mandatory, minimum terms (standards) and those terms that are merely default provisions (or guidelines) that employers and employees can agree to override. Most employment laws, including workplace safety laws, create standards and are thus objectionable to the L&E scholars.

Willborn (1988) articulated the standard economic objections to mandatory terms. Employers will treat newly imposed standards like exogenous wage increases and in the short run will respond by laying off workers. In the long run, employers will try to respond to mandates by lowering the wage. The final wage–benefits–standards employment package will make workers worse off than they were before the imposition of standards – otherwise the employers and workers would have bargaining for the package without legal compulsion.

Evidence on the Effects of OSHA Standards

Shapiro (2009) concluded that the studies of OSHA's activities to improve workplace safety produced inconsistent results. For example, Viscusi (1992) found that OSHA inspection activity reduced the lost workday rate by 1.5–3.6% at the industry level, but he indicated that other studies at this level of aggregation found no such effect. There were also conflicting results from studies at the individual-plant level. For example, Gray and Scholz (1991) found that inspections imposing a penalty reduced injuries, while Ruser and Smith (1991) found no such effect. On particular interest, Gray and Mendeloff (2005) found a decline over time in the effect of OHSA inspections on injury rates, with insignificant reductions in the most recent period in their study (1987–91).

Overall, the evidence suggests that the Occupational Safety and Health Act (OSHAct) has done little to improve workplace safety, thus lending more support to the L&E theory than to the government mandate theory. OSHA's ineffectiveness in part may be due to the lack of inspection activity, since Weil and Pyles (2005) note that the annual probability a US workplace will be inspected is well below 0.001. But the evidence also suggests that allocating additional resources to plant inspections may be imprudent, given the mixed results of inspections on safety.

In addition to the questionable effectiveness of OSHA inspections, some standards promulgated by OSHA have been criticized as excessively stringent. Viscusi (1996) examined OSHA standards using an implicit value of life of $5 million (derived from the compensating wage differential studies) as the standard for an efficient regulation. Four of the five OSHA safety regulations, but only one of the five OSHA health regulations adopted as final rules, had costs per life saved of less than $5 million. This evidence caused Burton and Chelius (1997) to provide a strong critique of the government mandate theory:

> To be sure, cost-benefit analysis of health standards issued under the OSHAct is not legal, and so those standards that fail the cost-benefit test (considering both the lives saved plus injuries and illnesses avoided) do not violate the letter and presumably the purpose of the law. But to the extent that the rationale offered by the government mandate theorists for regulation of health is that workers lack enough information to make correct decisions and therefore the government is in a better position to make decisions about how to improve workplace health, the evidence on the variability of the cost/benefit ratios for OSHA health standards is disquieting. Rather than OSHA standards reflecting interventions in the marketplace that overcome deficiencies of the marketplace, the explanation of why the stringency of regulation varies so much among industries would appear at best to be a result of technology-based decisions that could well aggravate the alleged misallocation of resources resulting from operation of the market and at worst could reflect relative political power of the workers and employers in various industries.

Conclusions

This article suggests that understanding the economics of workplace safety involves a rather eclectic mix of theories. Burton and Chelius (1997) were least impressed with the arguments and evidence pertaining to the pure neoclassical economics and the government mandate theories. They concluded that, among the other economic theories pertaining to safety, no single theory provides an adequate understanding of the causes and prevention of workplace accidents. Rather,

a combination of the theories, though untidy, is needed. Their conclusion has stood the test of time.

Same-Sex Sexualities in Turkey

Cenk Özbay, Bogazici Universitesi, Bebek, Istanbul, Turkey

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article examines the background and the current situation of same-sex sexualities in Turkey. First, a short recent history of homosexuality in the nation and the ways it has been represented are explained. Then, the most significant factors that reshape contemporary Turkish same-sex sexualities, namely, Islam, social class, and the role of the state are expounded. Finally, some of the emergent problems and issues that gay, lesbian, bisexual, transgender, and queer people in Turkey have to deal with are contrasted to their persistence at seeking respect.

A Short History of Same-Sex Sexualities in Turkey

Following a social constructionist perspective on same-sex sexualities and homosexual identities throughout modern history (D'Emilio, 1998; Nardi and Schneider, 1998; Plummer, 1992; Seidman, 2009; Weeks, 1990), one can discern an ambiguous time in Turkish history when there were no sexual self-identities or medical diagnosis of sexual 'abnormalities,' but same-sex sexual acts took place and virtually everybody had knowledge about them. This undocumented and thus ambiguous period starts from the late Ottoman Empire and continues for 100 years or more into the temporal realm of modern Turkish Republic, which was founded in 1923. The new republic radically transfigured almost all spheres of social, cultural, and political public life via various developmentalist projects including Europeanization, secularization, westernization, and modernization. Not only the empire was abolished and a new nation with the nation-state was created but also a new, modern subject-citizen was formed under the influence of Enlightenment ideals by state discourses, policies, and practices. In spite of this grand transformation, same-sex sexual acts, or the type of 'the homosexual,' were not explicitly monitored, regulated, named, or criminalized by the new regime. Although it worked meticulously on the structure of the nuclear family, the role of women in public and private spheres, and the gendered politics of representation (Arat, 1997; Sirman, 2005), the modern revolution in Turkey was seemingly too busy to deal with, cure, ban, or intervene into homosexuality. Same-sex sexual activities became a significant part of the abject, invisible yet connived urban underground culture. Contemporary scholars can trace this hazy time period through local and foreign historians' work as well as novels and other literary forms. Among others, the great Turkish author Kemal Tahir's numerous novels and stories and the social historian Resat Ekrem Kocu's unfinished yet marvelous *Encyclopaedia of Istanbul* (1946) and his other books can reveal this unnamed yet fully experienced sexual riptide.

After a relatively insipid period in terms of homosexuality in the 1950s, the famous singer Zeki Muren became the first queer public figure in the history of the country in 1960s. In the beginning of his career, he was enacting a kind of alternative masculinity that contradicted with the hegemonic displays of manhood of its time. Later he started to destabilize gender and sexual norms more manifestly, and continued that until his death in 1991. People loved him as if he was a national hero and called him 'pasha,' a title used for the very masculine military leaders, despite the fact that he was not related emotionally or sexually to women and performed at stage in women's clothes with heavy makeup on his face. For most of his lifetime, he was an open transvestite and clandestine homosexual, a well-respected queer king (Özbay, 2009).

Despite his exceptional queer public display, Muren was not alone in enjoying a homosexual lifestyle in Turkey. The Beyoglu district of Istanbul has long been the focal point of queer lives in Turkey (Oz, 2009; Yuzgun, 1986, 1993). The country's first popular 'gay bar' Vat-69 (opening year 1975) and almost all its successors have been located in Beyoglu and vicinity. By attending to these bars as well as specific public beaches, parks, and Turkish baths at certain times, a new, distinct, modern homosexual person, who is located within a web of same-sex sexual relations instead of conventional family ties and collegial sociabilities, started to emerge in Istanbul after 1960s.

Another crucial figure in this particular history is also a singer, Bulent Ersoy. After becoming immensely popular in the late 1970s as an apparently homosexual man, in 1981 she became transsexual through a sex reassignment surgery. Although Muren's subverting queer performance was never oppressed by the state, Ersoy was legally banned to perform at stage by the postcoup military government. She was exiled to Germany until 1988 when the new, liberal government put an end to the prohibition. In contrast to Muren's highly adaptable, almost officially sanctioned transvestism, her radical transgenderism with the narratives about the surgeries and the bodily transformation, and the political conflict with the military power, made Ersoy a trenchant symbol of gender and sexual struggle that is still effective in the 'structure of feeling' about homosexuality or same-sex intimacies in Turkey (Yuzgun, 1986; Hocaoglu, 2002). For homosexuals, the 1980s was also the decade full of brutal police patrols, torture in police stations, harassment in public spaces and bars, and the new stigma that came with the first human immunodeficiency virus infection/acquired immunodeficiency syndrome (HIV/AIDS) cases.

By the late 1980s, the incipient neoliberalization of the economy, further integration to the Western world, and the strong tides of globalization paralleled public Turkish culture becoming gradually demilitarized. Along with these changes,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10219-3

modern gay men emerged in major Turkish cities. They tended to imitate a Euro-American style of gayness, embodied body-oriented gay masculinity, and declared a symbolic war against the feminine public image of homosexuality, which more or less stemmed from the popular transgender singers (Hocaoglu, 2002; Tapinç, 1992). A more surreptitious but better organized urban gay culture flourished in this period. Men who have sex with men started to identify themselves as 'gay' as in English, having sex with other gay men, having emotional and long-term relationships, desiring and emulating a straight-looking bodily demeanor, and coming together not only for purposes of sex and joy but also for political commitment and sexual activism against homophobia. The first commercial movies regarding the issues of same-sex sexuality were produced in the Turkish film industry in the 1980s (Oztek, 2007) and homosexual stories started to reappear in Turkish novels, after a long period of silence. Representations of homosexuality in film and novel increased steadily in the 1990s and notable examples of queer art became well known such as gay authors Murathan Mungan's and Selim Ileri's books and Ferzan Ozpetek's critically acclaimed first film Steam-The Turkish Bath (1997).

Gay life in the recent history of modern Turkey reached its peak in the early 2000s, followed by its eventual decline in terms of its visibility and diversity in social and physical spaces in the metropolitan areas. Numerous gay (and to a certain extent lesbian) cafes, bars, and clubs opened during those years in Istanbul, the businesses were full with hundreds of avid homosexual people, the popular press and the news media had quite positive coverage about the glittering gay bars and their clientele, academic publications and research accounts were beginning to be published, sexual activists became more discernable and respected, and the confusion that masses had about the meaning of the concepts gayness and transgenderism vanished a little bit (Hocaoglu, 2002; Bereket and Adam, 2006). In addition to the self-assured gay men, lesbians became for the first time visible and came together as a separate social group to discuss their own problems that might be different than gay men's (Basdas, 2007; Özbay and Soydan, 2003; Savci, 2011).

In this very formation of modern gay and lesbian social identity in Turkey, three different developments played important roles. The first one was the gradual decrease and the eventual end of police raids and violence toward homosexuals and transgenders (Oz, 2009; Yuzgun, 1993). In this sense, it was deemed a little bit more acceptable and feasible to open and manage gay commercial venues, especially in metropolitan areas. Visitors in these queer businesses did not have fear of being exposed to the police when they were socializing. The second point was about the change in the attitude of the newspapers and the news media. Broadly speaking, the marginalizing, otherizing, and even dehumanizing language was dropped off and gays and lesbians started to appear in the pages through their own agendas and words within a framework of tolerance and esteem (Savci, 2011). A third cornerstone in this process was the diffusion of the Internet. It enabled gay men and lesbians to become connected to each other, social organizations and groups, and the world, without being revealed in front of the heterosexual society or having to come out of the closet unwillingly and uncontrollably (Hocaoglu, 2002; Özbay and Soydan, 2003). In the beginning, European dating Web sites brought large numbers of people together online and then Turkish Web sites were founded and replaced the European ones, became even more popular in urban zones and in the provincial towns. Maybe for the first time in the modern history, being gay and engaging into same-sex sexual activities had no social costs and consequences in Turkey.

Current Situation

Today, Turkey is one of the few countries in which homosexuality or counternormative sexualities are legal yet they are subjugated by state institutions, including the restrictive actions of police forces and public prosecutors (Oz, 2009; Savci, 2011). A simultaneous double life is experienced in terms of same-sex sexualities. On the one hand, the Turkish state and society are becoming more conservative, religious, and oppressive, in the sense that they forbid not only certain types of sexualities but sexuality itself and all its public manifestations are being constructed as taboo. On the other hand, same-sex sexualities are performed as they are tolerated within the zones of exception, especially in certain neighborhoods of the major metropolitan areas. These urban areas, under strict surveillance, provide social and physical spaces in which queer citizens engage same-sex sexualities and experience gay sociabilities while the state authorities are able to watch and govern the flow of homosexuals outside those areas. In this double configuration of same-sex sexual cultures, tolerance and intolerance, respect and intervention, freedom and restriction, grassroots diversity and superimposed uniformity, amalgamate by the participation of the state, the heterosexual public and gay men and lesbians as condoned exceptions (Basdas, 2007; Bereket and Adam, 2006, 2008; Özbay, 2010; Özyegin, 2012).

Subjects who have same-sex inclinations promulgate their own characteristics of flexibility, versatility, multifariousness, adaptability, discretion, self-centeredness, and even a precarious insincerity, in order to navigate within this compelling binary social structure that oscillates between a globalizing tendency for multiculturalism and an imagined insular isle of normality and undemocratic homogeneity (Özbay, 2010). The first step in this process is the formation of modern, Western, Euro-American gay and lesbian identities. These people construct a self-image that does not strive to hide their sexual identities and actions; on the contrary, as the Western role models suggest, coming out strategies and narratives play a crucial role in constituting who they really are and to what extent they internalize gay identities (Bereket and Adam, 2006; Hocaoglu, 2002; Özbay and Soydan, 2003; Özyegin, 2012). In this Westernized view of sexuality, there is a neat border between heterosexual and homosexual affect, culture, eroticism, and identity. A person is either gay or straight and the definitions are exact and stabilized.

There are factors complicating this supposedly neat, yet never neutral, division between what is homosexuality and what is heterosexuality. One of the most significant of them is the capacities of Islam. Islamic doctrines clearly prohibit same-sex sexual acts. Some of the most popular religious discourses and interpretations, as well as the religious public, openly deny

and ostracize gay men and lesbians as sinful people. This otherizing, robust antigay position is visible at least for the Sunni majority, while for the Alevi minority of Islam the attitude toward homosexuality is rather vague but supposedly more democratic and flexible. As Islam is not singular and unified at almost any subject, it has also multiple perspectives and principles about homosexuality. Despite the lack of elaborate discussions about religion and homosexuality as in the case of Christianity, homosexual citizens in Turkey have to deal with religion in their everyday lives and, to a certain extent, they have to find a satisfying answer to the inescapable question of whether they had faith (Bereket and Adam, 2008). Mostly, gay men and lesbians reconstruct themselves as entirely outside of the religious domain, believing in God but disconnecting from religious practices and developing a tacit silence, while some of them unmistakably reject religious and belief systems (Hocaoglu, 2002; Özbay and Soydan, 2003).

Another critical factor that shapes the current homosexual mise-en-scène in Turkey is class, which is not entirely independent from the social organization of religion in Turkish society. As it signifies a modern, global, refined, European, elite person whose cultural capital is sufficiently high, the term gay has a certain middle and upper class connotation in the Turkish vernacular. In other words, being gay in the Turkish context is not only about erotic subjectivity and sexual acts, but always a matter of social class (Armbrecht, 2001; Hocaoglu, 2002; Özbay, 2010). According to this classed understanding of sexuality, a person's erotic and intimate escapades cannot mark or stabilize the person's sexual identity; defining oneself as gay (or lesbian), sharing intimacy with self-identified homosexuals, or being a part of queer social environments are not enough alone to become gay. One needs to have a certain set of class criteria to achieve the proper, inherently modern gay identity. The most recurrent of these class signifiers are having or sharing an apartment in one of the decent middle–class areas of the city, being a college graduate or student, speaking foreign languages, adopting a secular lifestyle, following global cultural flows and fashions, traveling abroad, embodying and performing a specific style that is imbued with consumerism, self-care, and masculinity (at least for men). Being gay in this very setting is translated into becoming gay through utilizing cultural capital and mastering symbolic codes and then buoyantly sustaining it.

What happens when one has same-sex sexual affinities but for class reasons cannot follow the right codes of the middle upper–class gay notion? If he is more masculine and has a straight-acting aura then he is tagged as 'varos.' Varos in popular Turkish means both the destitute neighborhoods of informal housing and the poor, working class people who live in these areas. The word varos has obviously negative overtones and it is generally used in a derogatory sense. However, in the Turkish gay slang, varos is transformed into a word that signifies poverty and the lack of middle-class values, while it also highlights robust virility and an authentic, uncontaminated masculinity (Özbay, 2010). In this sense, the Turkish case bears a resemblance to the contexts in other countries in which the power of working-class masculinity defines or rejects sexual identities, labels, and communities (Aggleton, 1999; Barrett and Pollack, 2005; Parker, 1999). If the person who lacks the higher class qualities is more feminine, embodying an effeminate style, then this person is more easily deemed as a 'lubunya.' Lubunya is a term that was borrowed from transgender culture and it simply means sissy or unmanly (Berghan, 2007). Lubunya people are easier to match with the famous transgender singers' behavior by the public, and in some contexts they can be seen as candidates for future transvestism and transsexuality. Class for homosexuals in Turkey is deeply intertwined with desires that govern one's bodily presentations, gendered acts, and the ways of interpretation, which effect how they are related to other people.

Another significant aspect of contemporary homosexuality is the state institutions' intervention into the domain of morality, righteousness, and value through policy implementation at different levels. The most important aspect of this state intervention takes place in the compulsory military service (Biricik, 2009; Tarhan, 2008). According to law, all male Turkish citizens have to spend a certain amount of time in the army, serving for military purposes in the barracks. Only citizens with a predefined, extraordinary medical condition can avoid the service. Among the medical conditions that disqualify one from the service, in a very outdated psychological terminology, homosexuality is framed as an 'advanced psychosexual disorder' and thus people who are able to prove that they have this particular condition can waive the military service. After experiencing the awkward and torturous examinations held by the military officials, self-claimed homosexuals are entitled to receive a medical document called 'the rotten report,' which marks them as officially recognized homosexuals and tacitly excludes them from public life (Biricik, 2009). People, both gays and heterosexuals, believe that a person with the rotten report cannot work in state institutions, including public schools, and when they apply to jobs elsewhere their homosexuality will be known by the employers because of the circulation of the document between state and nonstate organizations. In other words, gay men in Turkey must find their way between two difficult strategies: perform the long compulsory military service as a closeted gay who travails to pass as straight, or get the rotten report, which has the potential to destroy their coming out strategies and their control over their personal and professional lives.

Despite the fact that the state, especially through the army, acknowledges the existence of homosexual citizens and labels them whenever it can, law does not recognize them otherwise and does not guarantee any sort of social rights that heterosexual citizens virtually have including but not limited to marriage, civil union contracts, and partnership benefits such as retirement, heritage, insurance, social security, and access to the corpse in case of death. No Turkish law specifically forbids discrimination on the basis of sexual orientation or sexuality in social institutions, government offices, or corporations. In fact, Turkey encourages discrimination through the distinct Ministry for Family and Social Policies (previously The State Ministry for Women), which reiterates the priority to protect families instead of individuals who opt for staying out of families; precludes alternative definitions of the family with a focus on definitions based on the conventional, traditional heterosexual family; and proselytizes reproductive policies. The previous head of the Ministry, Mrs Kavaf, even stated in 2010 that homosexuality was a disease that needed to be cured. Although she lost her chair

right afterward, this iteration is believed by many to reflect the official state attitude toward citizens with same-sex sexual inclinations. Supporting this assumption of state negativity, HIV/AIDS is still largely seen as a homosexual illness and the nongovernmental organizations that aim to prevent infection and to help HIV-positive people maintaining their lives are not supported by the state most probably because the sufferers as well as the charities about this illness are labeled as gay.

Issues, Visibilities, and Absences

Today, sexual minorities in urban Turkey are in great diversity consisting of gay men, lesbians, bisexuals, varos and lubunya individuals, transgenders, bears, and queers, who are mostly from the younger generations and defend the fluidity not fixity of sexual identities in the original sense of the term in English (Cakirlar and Delice, 2012; Özbay, 2010; Özyegin, 2012; Savci, 2011). In addition to the matters that emerge at the intersection of sexuality, Islam, social class, military policy, and the state, homosexuals have other issues to deal with in the course of everyday life. Among these issues are the fierce or symbolic violence they face; the continuing (although decreasing) confusion between gay and transgender identities; murders of both gays and transgenders; the homophobic approach that popular press and even politicians do not hesitate to use out of blue; the limited availability and despicably low physical standards of queer spaces; the huge secrecy, concealment, and insecurity in their lives; the rigid top–bottom sexual duality in terms of physical penetration; the scarce academic and scholarly research about queer lives and sexualities; and the intense marginalization and exclusion experienced by those intellectuals who think or write about sexualities. Some of these issues are evidently common in multiple international cultures, while some are strictly local and unique to the Turkish context and history.

Despite these limits, the emergence and the rise of same-sex sexual or queer activism also deserved to be indicated. Lambda and Kaos, in Istanbul and Ankara, respectively, have been active since early 1990s and they have improved a lot in terms of visibility and respectability. Queer college students at different campuses started to come together in the 2000s and they are still the most powerful group regarding the mobilization of young people against homophobia and heteronormativity. Turkey is a conservative and religious country and its politicians, whether from left or right wings, have traditionally stayed away from any sort of sexuality issues, starting with homosexual politics. Nevertheless, in the last couple of years, observers began to see a minor shift, especially in the two leftist political parties, the secular-modernist Republican People's Party (CHP) and the Kurdish Peace and Democracy Party (BDP). One BDP parliament member stated in the commission for rewriting the constitution that the less particular expressions such as everybody is equal in front of law should instead be more explicit and specifically declare that lesbians, gay men, bisexuals, and transgender individuals' situation need to be clearly mentioned in the new constitution. A group of CHP parliamentary members, among them former academicians, held a press conference with families of gay and transgender people and advocated for equal rights to sexual minorities. Another CHP congress member visited the gay and transgender section in a prison and talked to them about their demands. These are small but symbolically remarkable actions, exceptional and meaningful steps in the long process of having equal sexual citizenship and a democratic sense of identification and representation.

Recently, there has been a boom in queer artistic production and representation. Major novelists, among them Perihan Magden (2006, 2012), Duygu Asena (2006), and Elif Shafak (2007), as well as more independent literary figures, such as Niyazi Zorlu (2003) and Mehmet Murat Somer (2008, 2009), published thriving books while the queer filmmaker Kutlug Ataman's movie *Two Girls* (2007), which was adapted from Magden's novel, was noted as the first modern lesbian film that became mainstreamed in the Turkish popular culture. The respected director and university professor Can Candan produced a documentary about parents of queer children, *My Child* (2013), which became a national sensation and discussed widely in heterosexual public as well as among queer circles.

In terms of queer visibility, the greatest event that happens in Turkey is the Gay Pride celebrations that have taken place each June on the Istiklal Street in the Beyoglu district of Istanbul since 2001. Thousands of people, queer and straight, men and women and transgender, young and old, in all their diversity, gather and parade in attires that are quite counternormative for the standard Turkish taste, and act out, kiss each other, and dance together, which in other settings across the city in a manner that would typically create physically abusive, homophobic reaction. Onlookers can easily detect the carnivalesque collective spirit that inspires many otherwise closeted gays and lesbians, tired from oppression and concealment, protesting the heterosexist social values by their conspicuous presence in the heart of the city. The police, while normally harsh toward the protesters of any sort, do not attack the participants of the Pride, let the queer citizens walk, and maintain security through surveillance from distance.

At the end of the carnival, the burdensome conditions for queer people in Turkey recommence. There are serious taboos about same-sex sexualities in many spheres of social life. Sports, for example, especially football is one of them. The first and only out-of-closet gay football referee is not appointed to games any more by the national federation regardless of the support by many fans' associations. The theological circles, legislation, and the bureaucratic elites are rather passive and silent if not entirely against having queer members. Higher education is also dubious and not necessarily inclusionary – if not explicitly discriminating existing or prospective queer scholars. There is no out queer politician at either local or national level in Turkey. Except for a couple of elder actors and writers, there is no single esteemed, well-achieved, inspiring queer role model in the country.

Conclusion

The governing logic of the conservative, pious, neoliberal, corporate collective consciousness in Turkey avoids, forbids, condemns, marginalizes, and blacklists queer people and same-sex sexual acts. Although disempowered by much of culture and the state, these people strive to survive, make peace with the idea

of whom they are, congregate, socialize, and attempt to change the hostile social order in a bold and electrifying manner. Dynamics of globalization and transnational flows of ideas and expressions brought certain novelties, not only in Turkey but also in the Middle East as a whole, in terms of sexualities and intimacies (Özbay, 2012). It is difficult to say whether 50 years ago same-sex sexualities were freer in Turkey or nowadays they are more oppressed because it is almost impossible to fully grasp the clandestine nature of queer acts in the past. However, it is most certain that today one talks, thinks, and knows more about sexualities and in this discursive frame same-sex sexualities and queer identities occupy a great place. The Turkish case presents a twisted example simply because globalizing, more flexible, liberating currents are juxtaposed here with a more conservative, authoritarian, subjugating undertow. Thus, it is not entirely possible to exactly foresee which direction Turkish same-sex sexualities will take in the future, but it is obvious from the recent developments that the symbolic, social, and political struggle of queers against homophobia in Turkey has been ignited.

Abstract

Sampling methods have their roots in attempts to measure the characteristics of a nation's population by using only a part instead of the whole population, i.e., a census. The movement from the exclusive use of censuses to the at least occasional use of samples was slow and laborious. A watershed was the debate over representative methods and the rise of probability sampling, including the seminal 1934 paper of Jerzy Neyman. This article describes these developments as well as the impact in the United States of the results of this work on sample surveys, the contributions of statisticians working in government statistical agencies, and the subsequent establishment of random sampling and survey methodology more broadly.

Introduction

Sampling methods have their roots in attempts to measure the characteristics of a nation's population by using only a part instead of the whole population. The movement from the exclusive use of censuses to the at least occasional use of samples was slow and laborious. Two intertwined intellectual puzzles had to be solved before the move was complete. The first such puzzle was whether it is possible to derive valid information about a population by examining only a portion thereof (the 'representative' method). And the second puzzle concerned the method for choosing that portion. Issues of choice themselves fall into two categories: the structuring of the population itself in order to improve the accuracy of the sample, and whether to select the units for inclusion by purposive or random methods. This article considers the development of methods for the sampling of human populations. We begin by describing two antecedents of modern survey methods – the development of government statistics and censuses and the general development of statistical methodology, especially for ratio estimation. Then we deal with the movement from censuses to sample surveys, examining the debate over representative methods and the rise of probability sampling, including the seminal 1934 paper of Jerzy Neyman. We describe the impact in the United States of the results obtained by Neyman on sample surveys and the contributions of statisticians working in US government statistical agencies. We end with a brief description of the subsequent establishment of random sampling and survey methodology more broadly and examine some history of the movement from the study of the design of sampling schemes to the study of other issues arising in the surveying of human populations.

Antecedents of Modern Sample Survey Methods

In order to determine facts about their subjects or citizens, and more often about their number, governments have long conducted censuses. Thus, one set of roots of sample survey methodology is intertwined with the history of methods for census taking. The origins of the modern census are found in biblical censuses described in the Old Testament (e.g., see the discussions in Duncan, 1984 and Madansky, 1986) as well as in censuses carried out by the ancient Egyptians, Greeks, Japanese, Persians, and Romans (Taeuber, 1978). For most practical purposes we can skip from biblical times to the end of the eighteenth century and the initiation of census activities in the United States of America, even though there is some debate as to whether Canada, Sweden, or the United States should be credited with originating the modern census (Willcox, 1930).

The word statistics comes to us via the German word *Statistik*, introduced by Gottfried Achenwall in 1749, which derived from the Latin status is related to the word state (John, 1883). He used it to designate the analysis of data about the state, which in English was referred to as political arithmetic. In the eighteenth century, statistics was typically used in the context of data about society, often in what we have come to know as official statistics, but it also had other more specific applications in economics, demography, and politics. These uses of statistics lacked formal methodological techniques for gathering and analyzing data.

Another antecedent of sampling lies in the problem of estimating the size of a population when it is difficult or impossible to conduct a census or complete enumeration. Attempts to solve this problem even in the absence of formal sampling methods were the inspiration for what we now know as ratio estimation. These ideas emerged as early as the seventeenth century. For example, John Graunt (1620–74) used the technique to estimate the population of England from the number of births and some assumptions about the birth rate and the size of families. Graunt's research, later dubbed political arithmetic, was based on administrative records (especially parish records) and personal observation, as in his seminal work, *Natural and Political Observations Made Upon the Bills of Mortality*, published in 1662. To accomplish what Graunt did by assumption, others looked to hard data from subsets of a population. Thus, Sir Frederick Morton Eden, for example, found the average number of people per house in selected districts of Great Britain in 1800. Using the total number of households in Great Britain from tax rolls (and allowing for those houses missing from the rolls), Eden estimated the population of Great Britain as 9 million, a figure confirmed by the first British census in 1801 (Stephan, 1948).

Even earlier, in 1765 and 1778, civil servants published population estimates for France using an enumeration of the population in selected districts and counts of births, deaths, and marriages, for the country as a whole (see Stephan, 1948).

It was Pierre Simon de Laplace (1749–1827), however, who first formally described the method of ratio estimation during the 1780s, and he then employed it in connection with a sample survey that he initiated to estimate the population of France as of 22 September 1802. He arranged for the government to take a sample of administrative units (communes), in which the total population, y, and the number of registered births in the preceding year, x, were measured. Laplace then estimated the total population of France by $\hat{Y} = Xy/x$, where X was the total number of registered births. Laplace was the first to estimate the asymptotic bias and variance of $\hat{Y}$, through the use of a superpopulation model for the ratio $p = y/x$ (see Laplace, 1814). William Cochran (1978) describes this derivation and links it to results that followed 150 years later. Quetelet later applied the ratio estimation approach in Belgium in the 1820s but abandoned it following an attack by others on some of the underlying assumptions (see Stigler, 1986: pp. 162–166).

From Censuses to Surveys

The move from censuses to sample surveys to measure the characteristics of a nation's population was slow and laborious. Bellhouse (1988), Kruskal and Mosteller (1980), and Seng (1951) trace some of this movement, especially as it was reflected in the discussions regarding surveys that took place at the congresses of the International Statistical Institute (ISI). The move succeeded when investigators combined random selection methods with the structuring of the population and developed a theory for relating estimates from samples, however structured, to the population itself.

As early as the 1895 ISI meeting, Kiaer (1896) argued for a 'representative method' or 'partial investigation,' in which the investigator would first choose districts, cities, etc., and then units (individuals) within those primary choices. The choosing at each level was to be done purposively, with an eye to the inclusion of all types of units. That coverage tenet, together with the large sample sizes recommended at all levels of sampling, was what was judged to make the selection representative. Thus the sample was, approximately, a miniature of the population. Kiaer used systematic sampling in his 1895 survey of workers as a means of facilitating special tabulations from census schedules for a study of family data in the 1900 Norwegian census. Kiaer actually introduced the notion of random selection in his description of this work by noting that at the lowest level of the sample structure "the sample should be selected in a haphazard and random way, so that a sample selected in this manner would turn out in the same way as would have been the case had the sample been selected through the drawing of lots …" (Kiaer, 1897: p. 39).

The idea of less than a complete enumeration was opposed widely, and Kiaer presented arguments for sampling at ISI meetings in 1897, 1901, and 1903. Lucien March, in a discussion of Kiaer's paper at the 1903 meeting, formally introduced the concepts of simple random sampling without replacement and simple cluster sampling, although not using these names (Bellhouse, 1988).

Arthur Lyon Bowley did a number of empirical studies on the validity of random sampling, motivated at least in part by a 1912 paper by Francis Ysidro Edgeworth. Bowley used large sample normal approximations (but did not conceptualize what he was doing as sampling from a finite population) to actually test the notion of representativeness. Then, he carried out a 1912 sample survey on poverty in Reading, in which he drew the respondents at random (see Bowley, 1913), although he appears to have equated simple random sampling with systematic sampling (Bellhouse, 1988).

At about the same time, in what appears to be an independent line of discovery, Tchouproff and others were overseeing the implementation of sample survey methods in Russia, especially during World War I and the period immediately following it. This work was partially documented after the Russian Revolution in *Vestnik Statistiki*, the official publication of the Central Statistical Administration (Zarkovic, 1956, 1962). Even though there is clear evidence that Tchouproff had developed a good deal of the statistical theory for random sampling from finite populations during this period (see Seneta, 1985), whether he actually implemented forms of random selection in these early surveys is unclear. He later published the formulae for the behavior of sample estimates under simple random sampling and stratified random sampling from finite populations in Tchouproff (1918a,b, 1923a,b).

In a seemingly independent development of these basic ideas for sampling in the context of his work on agricultural experiments, Neyman in Splawa-Neyman (1923) described them in the form of the drawing of balls without replacement from an urn. In the resulting 1925 paper (Splawa-Neyman, 1925), he gave the basic elements of the theory for sampling from finite populations and its relationship with sampling from infinite populations. These results clearly overlapped those of Tchouproff, and 2 years later following Tchouproff's death, his partisans took Neyman to task for his lack of citation to the Russian work as well as to earlier work of others (see Fienberg and Tanur, 1995, 1996, for a discussion of the controversy).

By 1925, the record of the ISI suggests that the representative method was taken for granted, and the discussions centered around how to accomplish representativeness and how to measure the precision of sample-based estimates, with the key presentations being made by Bowley (1926) and in the same year by the Danish statistician Adolph Jensen. Notions of clustering and stratification were put forward, and Bowley presented a theory of proportionate stratified sampling as well as the concept of a frame, but purposive sampling was still the method of choice. It was not until Gini and Galvani made a purposive choice of which returns of an Italian census to preserve, and found that districts chosen to represent the country's average on seven variables were, in that sense, unrepresentative on other variables, that purposive sampling was definitively discredited among professional statisticians (Gini, 1928; Gini and Galvani, 1929). The notion of representative sampling lives on, however, especially in the modern era of Internet polling and sampling.

Neyman's (1934) Paper on Sampling

In their work on the Italian census, Gini and Galvani seemed to call into question the accuracy of sampling. Neyman took up their challenge in his classic 1934 paper presented before the

Royal Statistical Society, "On the two different aspects of the 'representative method'." In it, he compared purposive and random sampling, and concluded that it was not sampling that was problematic but rather Gini and Galvani's purposive selection.

Elements of synthesis were prominent in the paper as well. Neyman explicitly uncoupled clustering and purposive sampling, saying, "In fact the circumstance that the elements of sampling are not human individuals, but groups of these individuals, does not necessarily involve a negation of the randomness of the sampling" (1952: p. 571). He called this procedure, 'random sampling by groups' and pointed out that, although Bowley did not consider it theoretically, he used it in practice in London, as did O. Anderson in Bulgaria. Neyman also combined stratification with clustering to form 'random stratified sampling by groups,' and he provided a method for deciding how best to allocate samples across strata (optimal allocation). The immediate effect of Neyman's paper was to establish the primacy of the method of stratified random sampling over the method of purposive selection, something that was left in doubt by the 1925 ISI presentations by Jensen and Bowley. But the paper's longer-term importance for sampling was the consequence of Neyman's wisdom in rescuing clustering from the clutches of those who were the advocates of purposive sampling and integrating it with stratification in a synthesis that laid the groundwork for modern-day multistage probability sampling.

Surprisingly, for many statisticians the memorable parts of Neyman's paper were not these innovations in sampling methodology but Neyman's introduction of general statistical theory for point and interval estimation, especially the method of confidence intervals.

As pathbreaking as Neyman's paper was, a number of its results had appeared in an earlier work by Tschuprow (1923a, 1923b), in particular the result on optimal allocation in stratified sampling (see Fienberg and Tanur, 1995, 1996, for discussions of this point). The Danish mathematician Gram (1883) derived the method much earlier in a paper dealing with calculations for the cover of a forest based on a sample of trees. Gram's work has been rediscovered only in the twenty-first century and seems not to have been accessible to either Tchouproff or Neyman (see Merton, 1961/1973, for a discussion of instances of such 'multiples' in science).

Neyman provided the recipe for others to follow and he continued to explain its use in convincing detail to those who were eager to make random sampling a standard diet for practical consumption (e.g., see Neyman, 1952 for a description based on his 1937 lectures on the topic at the US Department of Agriculture Graduate School, as discussed below).

The Development of Random Sampling in the United States

One might have thought that the resolution of the controversy over the representative method and the articulation of the basic elements of a theory of sample surveys by Neyman would have triggered extensive application of random sampling throughout the world. Surprisingly, this was not the case. With some notable exceptions, for example, in England (see Cochran, 1939; Yates, 1946) and India, the primary application occurred in the United States and this led to a spate of new and important methodological developments.

As late as 1932, however, there were few examples of probability sampling anywhere in the US federal government (Duncan and Shelton, 1978) and the federal statistical agencies had difficulty responding to the demand for statistics to monitor the effects of the programs of President Franklin Roosevelt's New Deal. In 1933, the American Statistical Association (ASA) set up an advisory committee that grew into the Committee on Government Statistics and Information Services (COGSIS), sponsored jointly by ASA and the Social Science Research Council. COGSIS helped to stimulate the use of probability sampling methods in various parts of the Federal government, and it encouraged employees of statistical agencies to carry out research on sampling theory. For example, to establish a technical basis for unemployment estimates, COGSIS, and the Central Statistical Board which it helped to establish, organized an experimental Trial Census of Unemployment as a Civil Works Administration project in three cities, using probability sampling, and carried out in late 1933 and early 1934. The positive results from this study led in 1940 to the establishment of the first large-scale, ongoing sample survey on employment and unemployment using probability sampling methods. This survey later became known as the Current Population Survey and it continues to the present day.

Another somewhat indirect outcome of the COGSIS emphasis on probability sampling took place at the Department of Agriculture Graduate School where W. Edwards Deming, who recognized the importance of Neyman's (1934) paper, invited Neyman to present a series of lectures in 1937 on sampling and other statistical methods (Neyman, 1952). These lectures had a profound impact on the further development of sampling theory not simply in agriculture, but across the government as well as in universities.

Among those who worked on the probability-sampling-based trial Census of Unemployment at the Bureau of the Census was Morris Hansen, who was then assigned with a few others to explore the field of sampling for other possible uses at the Bureau, and went on to work on the 1937 sample Unemployment Census. After working on the sample component of the 1940 decennial census (under the direction of Deming), Hansen worked with others to redesign the unemployment survey based on new ideas on multistage probability samples and cluster sampling (Hansen and Hurwitz, 1942, 1943). They expanded and applied their approach in various Bureau surveys, often in collaboration and interaction with others, and this effort culminated in 1953 with the publication of a two-volume compendium of theory and methodology (Hansen et al., 1953a,b).

Cochran's (1939) paper, written in England and independently of the US developments, is especially notable because of its use of the analysis of variance in sampling settings and the introduction of superpopulation and modeling approaches to the analysis of survey data. In the 1940s, as results from these two separate schools appeared in various statistical journals, we see some convergence of ideas and results. The theory of estimation in samples with unequal probabilities of selection also emerged around this time (see Horvitz and Thompson, 1952; Hansen et al., 1985).

Statisticians have continued to develop the theoretical basis of alternative methods of probability sampling and statistical inference from sampling data since the middle of the twentieth century (see, e.g., Rao and Bellhouse, 1990; Sarndal et al., 1992). The issue of statistical inference for models from survey data remains controversial, at least for those trained from a traditional finite sampling perspective.

Market Research and Polling

The 1930s, and especially the period after World War II, however, saw a flowering of survey methodology in market research and polling, as well as in the social sciences more broadly. Initial stimulation came from a number of committees at the Social Science Research Council and social scientists such as Hadley Cantril, Paul Lazarsfeld, Rensis Likert, William Ogburn, and Samuel Stouffer (e.g., see Stephan, 1948; Converse, 1987 for a discussion). Stouffer actually spent several months in England in 1931–32, and learned about sampling and other statistical ideas from Bowley, Karl and Egon Pearson, and R.A. Fisher. He then participated in the Census of Unemployment at the Bureau of the Census.

Market research and polling trace their own prehistory to election straw votes collected by newspapers, dating back at least to the beginning of the nineteenth century. Converse (1987) points out, however, a more serious journalistic base; election polls were taken and published by such reputable magazines as the *Literary Digest* (which had gained a reputation for accuracy before the 1936 fiasco). Then, as now, election forecasting was taken as the acid test of survey validity. A reputation for accuracy in 'calling' elections was thought to spill over to a presumption of accuracy in other, less verifiable areas.

There was a parallel tradition in market research, dating back to just before the turn of the twentieth century, attempting to measure consumers' product preferences and the effectiveness of advertising. It was seen as only a short step from measuring the opinions of potential consumers about products to measuring the opinions of the general public about other objects, either material or conceptual. By the mid-1930s there were several well-established market research firms. Many of them conducted election polls in 1936 and achieved much greater accuracy than did the *Literary Digest*. It was the principals of these firms (e.g., Archibald Crossley, George Gallup, and Elmo Roper) who put polling – election, public opinion, and consumer – on the map in the immediate pre-World War II period.

The polling and market research surveys of Crossley, Gallup, Roper, and others were based on a sampling method involving 'quota controls,' but did not involve random sampling. Stephan (1948) observed the close link between their work and the method of purposive sampling that had gained currency much earlier in government and academic research circles, but which by the 1930s had been supplanted by random sampling techniques.

From Sampling Theory to the Study of Nonsampling Error

The 1940s saw a rapid spread of probability sampling methods to a broad array of government agencies. It was, however, only after the fiasco of the 1948 presidential preelection poll predictions (Mosteller et al., 1949) that market research firms and others shifted toward probability sampling. Even today many organizations use a version of probability sampling with quotas (Sudman, 1967).

Amidst the flurry of activity on the theory and practice of probability sampling during the 1940s, attention was being focused on issues of nonresponse and other forms of nonsampling error (e.g., see Deming, 1944) such as difficulty in understanding questions, or remembering answers, etc. A milestone in this effort to understand and model nonresponse errors was the development of an integrated model for sampling and nonsampling error in censuses and surveys, in connection with planning for and evaluation of the 1950 census (Hansen et al., 1951). This analysis-of-variance-like model, or variants of it, has served as the basis of much of the work on nonsampling error since.

Developments in sampling since the mid-twentieth century have to do less with the design of samples and more to do with the structuring of the survey instrument and interview. Thus, there has been a move from face-to-face interviewing to telephone interviewing (with the attendant problems connected with random-digit dialing), and then to the use of computers to assist in interviewing. Nonsampling errors continue to be studied broadly, often under the rubric of cognitive aspects of survey design.

In the early twenty-first century several challenges loomed for the survey effort. As the volume of surveys increased, response rates continued their decline, even for survey conducted for branches of the Federal Government (Curtin et al., 2005; Groves, 2006, 2011). A good deal of work was done to try to increase response rates, and more was done to evaluate the possible error introduced by nonresponse. In addition, as more of the population in the developed world moved from landlines to mobile phones, methods of sampling cell phones began to be explored. Such methods had to take into account two broad sets of issues. First, a mobile phone usually belongs to an individual, in contrast to a landline that typically belongs to a household. Hence the *ultimate sampling unit* is typically an individual, not a household, and many surveys need to be adjusted to take this difference into account. Second, because cell phone users, at least in the US, normally pay for incoming as well as outgoing calls, new issues of respondent cooperation arose, as did government regulations that forbade the use of automatic dialing devices to reach cell phones.

As telephone surveys became harder to carry out and developed greater nonresponse problems, researchers began exploring the possibility of using the Internet to carry out sample surveys. It became commonplace, even for government-sponsored surveys (for example, the NSF Survey of Doctoral Recipients), to give respondents the choice of responding by mail, phone, or the Internet. In addition, a new Internet survey mode was developed, where respondents were recruited via e-mail (sometimes based on a random sample of phone contacts) and formed a panel from which members were repeatedly recruited for surveys. At the time of preparation of this article, there is no clear consensus on the accuracy of these Internet panels. For an excellent set of articles on web surveys, see Couper and Miller (2008) and the special issue of the journal *Public Opinion Quarterly* to which that article is an introduction.

With the WWW and advances in computing and storage, we have entered the era of *big data*. Many believe that more data are better and that there no longer is the need for sampling and the statistical theory associated with it. 'Found data' such as those amassed on individuals from the WWW have many attractions, but there remains great value in examining carefully selected samples of Web pages instead of looking at the entire WWW. How to do this efficiently is one of the new challenges for sampling theory. Moreover, 'found data' are not a substitute for careful survey measurement on data gathered from a randomly selected subset of a well-defined population.

Sample Surveys: Cognitive Aspects of Survey Design

Judith M Tanur, Stony Brook University, Stony Brook, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Cognitive aspects of survey design refer to a research orientation that began in the early 1980s to integrate methods, techniques, and insights from the cognitive sciences into the continuing effort to render data from sample surveys of human populations more valid and reliable, and to understand systematically the threats to such reliability and validity. It was also intended to offer to cognitive scientists, especially cognitive psychologists, opportunities to use large-scale surveys to generalize and further test the results of their laboratory experiments.

Background and History

While a sample survey of human beings can be of good and measurable accuracy only if it is accomplished through probability sampling (*Sample Surveys: The Field* and *Sample Surveys: Methods*), probability sampling is only the first step in assuring that a survey is successful in producing results accurate enough for use in predicting elections, for gauging public opinion, for measuring the incidence of a disease or the amount of acreage planted in a crop, or for any of the other myriad of important uses that depend on survey data. Questions must be worded not only in ways that are unbiased, but also understandable to respondents and convey the same meaning to respondents as was intended by the survey's author. If the questions refer to facts about the past, they must be presented in ways that help respondents to remember the facts accurately and report truthfully. And interviewers must be able to understand respondents' answers correctly to record and categorize them appropriately.

These and other nonsampling issues have been of concern to survey researchers for many decades (e.g., Payne, 1951). Researchers were puzzled by the fact that changing the wording slightly in a question, sometimes resulted in a different distribution of answers and sometimes did not; worried that sometimes the context of other questions affected answers to a particular question, and sometimes did not; concerned that sometimes respondents were able to remember things accurately and sometimes were not. In the late 1970s and early 1980s, as survey data came to be used ever more extensively for public policy purposes, concerns for the validity of those data became especially widespread.

These concerns led to a cross-disciplinary research endeavor that would bring the insights and methods of the cognitive sciences, especially cognitive psychology, to bear on the problems raised by surveys, and that would encourage researchers in the cognitive sciences to use surveys as a means of testing, broadening, and generalizing their laboratory-based conclusions. Since then, work in the field has incorporated theories and viewpoints from disciplines not usually classified as the cognitive sciences, notably linguistics, conversational analysis, anthropology, and ethnography.

Described below are some of the practical and theoretical achievements of the movement.

These include methodological transfers from the cognitive sciences to survey research, especially so-called cognitive interviewing, the broad establishment of cognitive laboratories in governmental and nongovernmental survey research centers, theoretical formulations that account for many of the mysteries generated by survey responses, and practical applications to the development and administration of ongoing surveys. Some references appear at the close describing these achievements more fully and speculating on the future course of the field. Perhaps surprisingly, there is little to report on the hoped-for use of surveys to generalize the findings of the cognitive sciences, despite the encouragement of such authors as Wright and Loftus (1998).

Methodological Transfers

Much work in the field is rooted in a classic information processing model applied to the cognitive tasks in a survey interview. The model suggests that the tasks the respondent must accomplish, in rough order in which they must be tackled (although respondents go back and forth among them), are comprehension/interpretation, retrieval, judgment, and communication. These models have been intertwined with the earlier models of the survey interview as a social interaction (Sudman and Bradburn, 1974) through the efforts of such researchers as Clark and Schober (1992) and Sudman et al. (1996) to take into account both the social communication and individual cognitive processes that play a part in the survey interview.

Guided by this model, one of the earliest achievements of the movement to study cognitive aspects of survey design was the adoption of some of the methods of the cognitive psychology laboratory for the pretesting of survey questionnaires. In particular, these methods are aimed at insuring that questions are comprehensible to respondents and that the meanings transmitted are those intended by the investigator. They also can point to problems in retrieval and communication. Such cognitive pretesting includes 'think-aloud protocols,' in which specially recruited respondents answer the proposed questionnaire aloud to a researcher, and describe, either concurrently with each question or retrospectively at the end of the questionnaire, their thought processes as they attempt to understand the question and to retrieve or construct an answer. This is an

adaptation of protocol analysis, a technique developed by Ericsson and Simon (1980, 1993). Beatty and Willis (2007) argue that this cognitive interviewing is perhaps the most widespread and important outcome of the CASM movement. (CASM is the original acronym chosen for this movement, standing for cognitive aspects of survey methodology. The acronym was chosen purposefully to pun on the broad chasm researchers in the diverse fields would have to bridge in order to work together.) They offer a review of the range of different types of cognitive interviewing used in practice.

Also used is behavioral coding, based on procedures originally developed by Cannell and coworkers (e.g., Cannell and Oskenberg, 1988), which note questions for which respondents ask for clarification or for which their responses are inadequate. Other methods include reviews of questionnaires by cognitively trained experts, the use of focus groups, and for questionnaires that are automated, measures of response latency. Detailed descriptions of these methods and their applicability to detect problems at various stages of the question answering process appear in Sudman et al. (1996), Schwarz and Sudman (1996), and Forsyth and Lessler (1991).

Interviewer Behavior

Although survey interviewing began with investigators themselves merely going out and having conversations with respondents, as the survey enterprise aspired to greater scientific respectability and as it became sufficiently large scale so that many interviewers were needed for any project, standardized interviewing became the norm. Printed questionnaires were to be followed to the letter; interviewers were instructed to answer respondents' requests for clarification by merely rereading the question or by saying that the meaning of any term is 'whatever it means to you.' While it is probably true that skilled interviewers have always deviated from these rigid standards in the interest of maintaining respondent cooperation and getting valid data, the robotlike interviewer delivering the same 'stimulus' to every respondent was considered the ideal. Working with videotapes of interviews for the National Health Interview Survey and for the General Social Survey and using techniques of conversational analysis, Suchman and Jordan (1990) showed that misunderstandings frequently arose because of the exclusion of normal conversational resources from the survey interview, and that these misunderstandings resulted not only in discomfort on the part of respondents, but also resulted in data that did not meet the needs of the survey designer. Suchman and Jordan recommended a more collaborative interviewing style, in which interviewer and respondent work together to elicit the respondent's story and then fill in the questionnaire. Note that this recommendation applies almost exclusively when the information sought is about the respondent's activities or experiences rather than about his/her attitudes or opinions. Both theoretical and practical advances have followed on these insights.

On a theoretical level, several researchers have used variants of the 'cooperativeness' principle advanced by Grice (1975) to help explain some of the anomalies that have puzzled survey researchers over the decades. Many are understandable as respondents bringing to the survey interview the communicative assumptions and skills that serve well in everyday life. The maxims of the cooperativeness principle require a participant in a conversation to be truthful, relevant, informative, and clear (Sudman et al., 1996: p. 63). Thus, for example, it has long been known that respondents are willing to report on their attitudes toward fictitious issues or nonexistent groups, and investigators have taken this willingness as evidence of the gullibility of respondents and perhaps of the futility of trying to measure attitudes at all. But to 'catch on' to the 'trick' nature of such a question, a respondent would have to assume that the interviewer violated all the maxims of the cooperativeness principle. Parsimony suggests, instead, that the respondent would assume that the interviewer knew what he or she was talking about, and answer accordingly. Several puzzles about context effects, discussed below, also seem understandable in light of Grice's maxims.

On a practical level, freeing interviewers to be more conversational with respondents is not costless; when interviewers explain more, interviews take longer, and are thus more costly in interviewers' wages and respondents' patience. Schober and Conrad (e.g., 1997) have embarked on a program of research that has demonstrated that conversational interviewing generates better data than does standardized interviewing when the mappings of the respondent's experiences onto the survey's concepts are complicated, but indeed at the cost of longer interviews. Perhaps a compromise might be to seek a point between fully standardized and fully conversational interviewing that balances the benefits in accuracy to be gained by a more conversational style with the costs in interview length. Conrad and Schober (e.g., 2008) also explore how endowing an animated figure in a Web-based interview with conversational abilities to prompt the respondent with definitions affects respondent accuracy.

Factual Questions versus Questions about Attitudes or Opinions

The distinction between questions that ask respondents to report on facts, usually autobiographical, and those that ask for an attitude or an opinion has been an important one in survey research. Indeed, the explicit origins of the movement to study cognitive aspects of survey design lie in a desire to improve the accuracy of factual reports from respondents; the extension of concern to attitudinal questions came somewhat later, although such a concern was certainly prefigured by the work reported in Turner and Martin (1984). The distinction remains important for interviewer behavior, in the sense that the kinds of conversational interviewing being investigated are designed to help respondents better comprehend the intent of the question and to recall more accurately their experiences. Interviewer interventions designed for these purposes, useful when the question is aimed at getting a factual report, might well bias the respondent's answer when the aim of the question is to elicit an attitude or opinion. The distinction is also valid in the sense that the cognitive theories about autobiographical memory that have been used to understand problems of the recall of factual information are less applicable to attitudes and opinions, and the cognitive techniques that have been

developed to aid respondent recall for autobiographical questions are not appropriate for the recall of attitudes or opinions. But in important ways the distinction obscures similarities between the two types of questions, as will be discussed in the section on context effects, below.

Improving the Accuracy of Factual Reports

Very often, survey questions ask for the frequency with which a respondent has accomplished a behavior (e.g., visited a doctor) or experienced an event (e.g., had an illness) during a specified time period (usually starting sometime in the past and ending with the date of the interview) called the reference period. Thus, the respondent, having understood what events or experiences should be included in the report, has a twofold task; he or she must recall the events or experiences, and also determine whether those events or experiences fell inside the reference period. Theories from the cognitive sciences about how experiences are stored in autobiographical memory and retrieved therefrom have been marshaled to understand both phases of the respondent's recall task and to improve their accuracy.

In a phenomenon called 'telescoping,' respondents are known often to move events or experiences forward in time, reporting them as falling within the reference period, although in fact they occurred earlier. One of the earliest contributions to the literature on cognitive aspects of survey design was the proposal of a technique dubbed 'landmarking' to control telescoping (Loftus and Marburger, 1983). Here, rather than inquiring about the last 6 months or the last year, a respondent is supplied with (or is asked to supply) a memorable date, and then is asked about events or experiences since that date. (For example, the respondent might be asked to report events since a public event, such as a holiday, or since a private event, such as a birthday.) The related concept of bounding is also useful in controlling telescoping. In a panel survey, in which respondents are interviewed repeatedly at regular intervals, informing them of the events or experiences reported at the last interview will prevent such events or experiences from being placed in the time period between the previous interview and the current one. An analogous technique useable in a single interview is the two-time frame procedure in which the respondent is first asked the report events or experiences during a long reference period (e.g., the last 6 months) and then for a shorter period that is really of interest to the investigator (e.g., the last 2 months). This technique seems both to relieve the pressure on respondents to report socially desirable events or experiences and to stress the interviewer's interest in correct dating, encouraging respondents to strive for greater accuracy. A theoretical explanation of telescoping, taking into account the workings of memory for the storage of timing and the effects of rounding to culturally stereotypical values (e.g., 7, 10, or 30 days), is provided by Hutenlocher et al. (1990).

The task of counting or estimating the number of events or experiences in the reference period can also provide a challenge to the respondent. Issues of frequency, regularity, and similarity influence whether the respondent is likely to actually count the instances or to employ an estimation strategy, as well as influence whether counting or estimation is likely to be more accurate. In general, respondents are more likely to retrieve from memory and count events or experiences if their number is few and to estimate if their number is large. But regular events (e.g., going to the dentist every 6 months) and similar events (e.g., trips to the grocery store) are more likely to be estimated. And investigators have found that estimation (perhaps by retrieving a rate and applying that rate to the length of the reference period) is usually more accurate, than the attempt to retrieve and count regular, similar events or experiences. For a full discussion of these issues, see Sudman et al. (1996).

Context Effects

Context effects occur when the content of the questions preceding a particular question (or even following that question in a self-administered questionnaire in which the respondent is free to return to earlier questions after reading later ones) influence how some respondents answer that question. The understanding of the term has been broadened to include also the effects on the distribution of responses of the response categories offered in a closed-ended question. Investigators have used the maxims of Grice's cooperativeness principle to approach a systematic understanding of these effects, which have seemed mysterious for many years. Full treatments of these issues may be found in Sudman et al. (1996) and Tourangeau (1999); by necessity only some selected findings can be presented here.

A pair of puzzling context effects that have fascinated researchers for years are assimilation effects and contrast effects. An assimilation effect occurs when the content of the preceding items moves the responses to the target item in the direction of the preceding items; a contrast effect occurs when the movement is in the opposite direction. These effects can now be understood through the inclusion/exclusion model of the judgment process in survey responding, proposed by Schwarz and Bless (1992). The model holds that when a respondent has to make a judgment about a target stimulus, he or she must construct a cognitive representation, not only of the target stimulus, but also of a standard with which to compare the target stimulus. To construct these representations, respondents must retrieve information from memory; since not all information in memory can be retrieved, respondents retrieve only that which is most easily accessible. And information can be accessible either because it is 'chronically' accessible or because it is temporarily accessible; it is the temporary accessibility of information that is affected by the context of the question. Positive temporarily accessible information supplied by the context and included in the representation of the target will render the judgment of the target more positive: negative context information thus included will render the judgment more negative. Both these processes produce assimilation effects. Contrast effects are created when the context suggests that information be excluded from the representation of the target, or included in the representation of the standard to which the target is to be compared. For example, Schwarz and Bless (1992) were able to manipulate the frequency of positive evaluations of a political party by using a reference to a popular politician in a preceding question. They were able to create an assimilation effect, resulting in more positive evaluations, by encouraging respondents to include the politician in their representations of the party (by having them

recall that the politician had been a member of the party). They were also able to create a contrast effect, resulting in less positive evaluations of the political party, by encouraging respondents to exclude the politician from their representation of the party (by having them recall that his present position took him out of party politics). The model predicts inclusion of more information when the target is a general question, thus encouraging assimilation effects; it also predicts contrast effects when the target is narrow. Thus, a preceding question about marital happiness seems to result in higher reports of general happiness for those who are happily married, but lower reports of general happiness for those who are unhappy in their marriages. This influence of the preceding question can be eliminated by having respondents see the questions about marital happiness and general happiness as part of a single unit (either by an introduction that links the two questions or by a typographical link on a printed questionnaire); then, in obedience to the conversational maxim that speakers should present new information, respondents exclude their marital happiness from their evaluation of their general happiness.

Similar recourse to conversational maxims helps explain the influence of the response alternatives presented in closed-answer questions on the distribution of responses. For example, Schwarz et al. (1985) found that 37.5% of respondents reported watching television (TV) for more than two and a half hours a day when the response scale ranged from 'up to $2^1/_2$ h' to 'more than $4^1/_2$ h,' but only 16.2% reported watching more than two and a half hours a day when the response scale ranged from 'up to $^1/_2$ hour' to 'more than $2^1/_2$ hours.' Respondents take the response scales to be conversationally informative about what typical TV watching habits are and calibrate their report accordingly.

Some Achievements of the Movement to Study Cognitive Aspects of Surveys

The Impact of Theories

Perhaps the most profound effect of the movement to study cognitive aspects of survey design is the introduction of theory into the research area. There has been space above to present only a few of the many such theoretical advances, but their utility should be clear. For example, consulting the maxims of cooperativeness in conversation gives us a framework for predicting and preventing response effects. In the same sense, the inclusion/exclusion model, much more fully developed than is presented here, makes predictions for what to expect from various manipulations of question ordering and content. These predictions offer guidance for the experimental advance of the research domain, and their testing systematically advances the knowledge, both of the phenomena and of the applicability of the theory.

The Cognitive Laboratories and Their Impact

Cognitive interviews in laboratory settings have become standard practice in several US government agencies (including the National Center for Health Statistics, the Bureau of Labor Statistics, and the Census Bureau), as well as in government agencies around the world, and at many academic and commercial survey organizations. Work in these laboratories supplements the usual large-scale field pretests of surveys. For illustrative purposes, it is worth describing two major efforts at US government agencies.

The Current Population Survey (CPS) is a large-scale government survey, sponsored by the Bureau of Labor Statistics and carried out by the Census Bureau. From interviews with some 60 000 households monthly are derived major government statistical series, including the unemployment rate. In the early 1990s, the CPS underwent its decennial revision, this time using the facilities of the government cognitive laboratories as well as traditional field testing of proposed innovations. In particular, this research found that the ordering and wording of the key questions regarding labor force participation caused some respondents to report themselves as out of the labor force when in fact they were either working part time or looking for work. It also found that the concept of layoff, which the CPS takes to mean temporary furlough from work with a specific date set for return, was not interpreted that way by respondents. Respondents seemed to understand 'on layoff' as a polite term for 'fired.' Appropriate revision of these questions, followed by careful field testing and running the new and old versions in parallel for some months resulted in estimates of the unemployment rate in which policy makers and administrators can have greater confidence. More details can be found in Norwood and Tanur (1994).

The US Decennial Census has always asked for a racial characterization of each resident. Originally designed to distinguish whites (mostly free) from blacks (mostly slaves) for purposes of counting for apportionment (the US Constitution originally mandated that a slave be counted as 3/5 of a man), the uses to which answers to the race identification question was put evolved over time. Civil Rights legislation starting in the 1960s designated protected groups, and it thus became important to know the population of such groups. At the same time, individuals were becoming both more conscious of their racial self-identification and less willing to be pigeonholed into a small set of discrete categories, especially as more individuals were self-identifying with more than one racial group. The 1990 Census asked two questions in this general area – one on racial identity followed by one on Hispanic ethnic identification. Experimental work (Martin et al., 1990) indicated that the ordering of these questions mattered to respondents. For example, when the Hispanic ethnicity question appeared first, fewer people chose 'other' as their racial category. This and other research made a convincing case that the complexity of Americans' racial and ethnic self-identification needed a more complex set of choices on the Census form. A 4-year program of research resulted in the conclusion that allowing respondents to choose as many racial categories as they believe apply to them is a solution superior to the provision of a multiracial category (see Tucker et al., 1996). (For more details on this and other census research see *Censuses: History and Methods*.) The 2000 Decennial Census (and that done in 2010) allowed respondents to choose as many racial categories as they wished; in 2000, approximately 2.4% of the population chose two or more races to identify with.

Conclusions

The movement to study cognitive aspects of surveys has thus given us some theoretical insights and practical approaches. Ideally, the hope of the movement to study cognitive aspects of survey design might well be to develop an overarching theory of the survey designing and responding process, but the field is currently far from that goal and may perhaps never be able to attain it. But the frameworks so far provided offer clear guidance of how to proceed in an effort to reach systematic understanding. Far fuller accounts of the results of the movement to study cognitive aspects of survey design and ideas of future directions can be found in Sirken et al. (1999a,b), Sudman et al. (1996), Tanur (1992), and Tourangeau et al. (2000).

Abstract

The theory for sample surveys has been developed using two theoretical frameworks: design-based and model-based. The design-based approach uses the probabilities with which units are selected for the sample for inference; in the model-based approach, the investigator hypothesizes a joint probability distribution for elements in the finite population, and uses that probability distribution for inference. In this article, the two approaches are described and compared, and guidelines are given for when, and how, one should perform a model-based analysis of survey data. The use of models for survey design is discussed briefly.

The theory for sample surveys has been developed using two theoretical frameworks: design-based and model-based. The design-based approach uses the probabilities with which units are selected for the sample for inference; in the model-based approach, the investigator hypothesizes a joint probability distribution for elements in the finite population, and uses that probability distribution for inference. In this article, the two approaches are described and compared, and guidelines are given for when, and how, one should perform a model-based analysis of survey data. The use of models for survey design is discussed briefly.

Inference in Sample Surveys

How does one generalize from individuals in a sample to those not observed? The problem of induction from a sample was much debated by philosophers, social scientists, and mathematicians of the eighteenth and nineteenth centuries, including Immanuel Kant, Charles Peirce, John Venn, and Adolphe Quetelet. In the early years of the twentieth century, many investigators resisted the idea of using survey samples rather than censuses for 'serious statistics' because of inference issues (*see* Sample Survey Methodology, History of). The debates involving official uses of sample surveys in these years resulted in the development of two philosophical frameworks for inference from a sample: design-based inference and model-based inference.

In design-based inference, first expounded systematically by Neyman (1934), the sample design provides the mechanism for inferences about the population. Suppose that a without-replacement probability sample (*see* Sample Survey Methodology, History of) of n units is to be taken from a population of N units. A random variable Z_i is associated with the ith unit in the population; $Z_i = 1$ if the unit is selected for inclusion in the sample, and $Z_i = 0$ if the unit is not selected. The joint probability distribution of $\{Z_1,\ldots, Z_N\}$ is used for inference statements such as confidence intervals (*see* Estimation: Point and Interval).

The quantity being measured on unit i, y_i, is irrelevant for inference in the design-based approach. Whether y_i is household income, years of piano lessons, or number of cockroaches in the kitchen, properties of estimators depend exclusively on properties of the random variables $\{Z_1, \ldots, Z_N\}$ that describe the probability sampling design. The Horvitz–Thompson (1952) estimator,

$$\sum_{i=1}^{N} Z_i y_i / \pi_i \qquad [1]$$

where $\pi_i = P(Z_i = 1)$, is an unbiased estimator of the population total $\sum_{i=1}^{N} y_i$; the variance of the Horvitz–Thompson estimator,

$$\sum_{i=1}^{N}\sum_{j=1}^{N} y_i y_j \left(\pi_i \pi_j\right)^{-1} \mathrm{Cov}\left(Z_i, Z_j\right)$$

depends on the covariance structure of $\{Z_1, \ldots, Z_N\}$.

The design-based approach differs from the inferential framework used in most other areas of statistics. There, y_i is the observed value of a random variable Y_i; the joint probability distribution of the Y_i's and proposed stochastic models allow inferential statements to be made. Following questions raised by Godambe (1955) about optimal estimation and survey inference, Brewer (1963) and Royall (1970) suggested that the same model-based frameworks used in other areas of statistics also be used in finite population sampling. Thompson (1997) summarized various approaches to prediction using models.

In the model-based approach to inference, the finite population values are assumed to be generated from a stochastic model. Regression models (*see* Linear Hypothesis: Regression (Basics)) are often adopted for this purpose: if covariates $x_{i1}, x_{i2}, \ldots, x_{ip}$ are known for every unit in the population, a possible model is

$$Y_i = \beta_0 + \beta_1 x_{i1} + \cdots + \beta_p x_{ip} + \varepsilon_i \qquad [2]$$

where the ε_i's are random variables with mean zero and specified covariance structure. The parameters β_j for $j = 0, \ldots, p$ may be estimated by standard techniques such as generalized least squares, and the regression equation used to predict the value of y for units not in the sample. Then the finite population total is estimated by summing the observed values of the y_i's for units in the sample and the predicted values of the response for units not in the sample.

To illustrate the two approaches, consider a hypothetical survey taken to study mental health status in a population of 10,000 women over age 65. A stratified random sample of 100 urban women and 100 rural women is drawn from a population of 6,000 urban women and 4,000 rural women over age 65. One response of interest is the score on a depression inventory. Let $\bar{y}_U$ denote the sample mean score for the urban women and let $\bar{y}_R$ denote the sample mean score for the rural women.

Under the design-based approach as exposited in Cochran (1977), $\pi_i = 1/60$ if person i is in an urban area and $\pi_i = 1/40$ if person i is in a rural area. Every urban woman in the sample represents herself and 59 other urban women who are in the population but not in the sample; every sampled rural woman represents herself plus 39 other rural women. The Horvitz–Thompson estimator for the mean depression score for the population is $N^{-1}\sum_{i=1}^{N} Z_i y_i/\pi_i$; here, the estimated population mean score under the stratified random sampling design is $0.6\bar{y}_U + 0.4\bar{y}_R$. A 95% confidence interval (CI) for the mean refers to the finite population: if a CI were calculated for each possible sample that could be generated using the sampling design, the selection probabilities of the samples whose CIs include the true value of the population mean depression score sum to 0.95. Inference refers to repeated sampling from the population, not to the particular sample drawn.

Any number of stochastic models might be considered in a model-based approach. Consider first a special case of the regression model in Eqn. [2], and assume that the ε_i's are independent and normally distributed with constant variance. Model 1 has the form $Y_i = \beta_0 + \beta_1 x_i + \varepsilon_i$, where $x_i = 1$ if person i is an urban resident and $x_i = 0$ if person i is a rural resident. The stochastic model provides a link between sampled and unsampled units: women who are not in the sample are assumed to have the same mean depression score as women with the same urban/rural status who are in the sample. Under Model 1, $\widehat{\beta}_0 = \bar{y}_R$ and $\widehat{\beta}_1 = \bar{y}_U - \bar{y}_R$ are the least squares estimates of β_0 and β_1. Thus the predicted value of y for each urban woman is $\bar{y}_U$, and the predicted value of y for each rural woman is $\bar{y}_R$. The model-based estimate of mean depression in this population is thus

$$\frac{1}{10,000}[100\bar{y}_U + 100\bar{y}_R + 5,900\bar{y}_U + 3,900\bar{y}_R] = 0.6\bar{y}_U + 0.4\bar{y}_R$$

With Model 1, the point and interval estimates of the finite population mean are the same as for the design-based approach. The 95% confidence interval is interpreted differently, however; 95% of CIs from samples with the same values of x_i that could be generated from the model are expected to contain the true value of $\beta_0 + 0.6\beta_1$.

In this example, model-based inference with Model 1 accords with the results from design-based inference. But suppose that the model adopted is Model 2: $Y_i = \mu + \varepsilon_i$. Then the predicted value of the response for all women in the finite population is $\bar{y} = (\bar{y}_U + \bar{y}_R)/2$, and the mean depression score for the finite population is also estimated by $\bar{y}$. If depression is higher among rural women than among urban women, the estimate $\bar{y}$ from Model 2 will likely overestimate the true mean depression score in the population of 10,000 women because rural women are not proportionately represented in the sample.

In the model-based approach, inference is not limited to the 10,000 persons from whom the sample is drawn but applies to any set of persons for whom the model is appropriate. Random selection of units is not required for inference as long as the model assumptions hold. If the model is comprehensive enough to include all important information, as in Model 1 above, then the sampling design is irrelevant and can be disregarded for inference.

The two types of inference differ in the conception of randomness. Design-based inference relies on the randomness involved in sample selection; it relates to the actual finite population, and additional assumptions are needed to extend the inferences to other possible populations. Model-based inference is conditional on the selected sample; the randomness is built into the model, and the model assumptions are used to make inferences about units not in the sample. Design-based inference depends on other possible samples that could have been selected from the finite population but were not, while model-based inference depends on other possible populations that could have been generated under the model but were not.

The approaches are not completely separated in practice. Rao (1997) summarized a conditional design-based approach to inference, in which inference is restricted to a subset of possible samples. Särndal et al. (1992) advocated a *model-assisted* approach, in which a population model inspires the choice of estimator, but inference is based on the sampling design. In the depression example, a model-assisted estimator could incorporate auxiliary information such as race, ethnicity, and marital status through a model of the form in Eqn. [2]; however, the stratified random sampling design is used to calculate estimates and standard errors.

Models in Descriptive and Analytic Uses of Surveys

Estimating a finite population mean or total is an example of a descriptive use of a survey: the characteristics of a particular finite population are of interest. In much social science research, survey data are used for analytic purposes: investigating relationships between factors and testing sociological theories. Data from the US National Crime Victimization Survey may be used to estimate the robbery rate in 1999 (descriptive), or they may be used to investigate a hypothesized relationship between routine activities and likelihood of victimization (analytic). In the former case, the population of inference is definite and conceivably measurable through a census. In the latter, the population of inference is conceptual; the investigator may well be interested in predicting the likelihood of victimization of a future person with given demographic and routine activity variables.

Smith (1994) argued that design-based inference is the appropriate paradigm for official descriptive statistics based on probability samples. Part of his justification for this position was the work of Hansen et al. (1983), who provided an example in which small deviations from an assumed model led to large biases in inference. Brewer (1999) summarized work on design-based and model-based estimation for estimating

population totals and concluded that a model-assisted generalized regression estimator (see Särndal et al. 1992), used with design-based inference, captures the best features of both approaches. Models must of course always be used for inference in nonprobability samples; they may also be desirable in probability samples that are too small to allow the central limit theorem to be applied for inference.

Lohr (1999, Chap. 11) distinguished between obtaining descriptive official statistics and uncovering a 'universal truth' in an analytic use of a survey. Returning to the depression example, the investigator might be interested in the relationship between depression score (y) and variables such as marital status, financial resources, number of chronic health problems, and ability to care for oneself. In this case, the investigator would be interested in testing a theory that would be assumed to hold not just for the particular population of 10,000 women but for other populations as well, and should be making inferential statements about the βs in model (2). The quantity for inference in the design-based setting is b_p, the least squares estimate of β that would be obtained if the x_is and y_i were known for all 10,000 persons in the finite population. The quantity b_p would rarely be of primary interest to the investigator, though, since it is merely a summary statistic for this particular finite population. In social research, models are generally motivated by theories, and a model-based analysis allows these theories to be tested empirically.

The generalized least squares estimator of β, $\widehat{\beta}_{LS}$, would be the estimator of choice under a pure model-based approach because of its optimality properties under the proposed model. This estimator is, however, sensitive to model misspecification. An alternative, which achieves a degree of robustness to the model at the expense of a possibly higher variance, is to use the design-based estimator of b_p. If the proposed stochastic model is indeed generating the finite population and if certain regularity conditions are met, an estimator that is consistent for estimating b_p will also be consistent for estimating β. Under this scenario, a design-based estimate for b_p also estimates the quantity of primary interest β and has the advantage of being less sensitive to model misspecification.

Regardless of philosophical differences on other matters of inference, it is generally agreed that two aspects of descriptive statistics require the use of models. All methods currently used to adjust for nonresponse (*see* Nonsampling Errors) employ models to relate nonrespondents to respondents, although the models are not necessarily testable. In small area estimation, sample sizes in some subpopulations of interest are too small to allow estimates of sufficient precision; models are used to relate such subpopulations to similar subpopulations and to useful covariates.

Models for Small Area Estimation

In small area estimation, a model is used to estimate the response in subpopulations with few or no sample observations. As an example, the US Current Population Survey (CPS) provides accurate statistics about income and poverty for the nation as a whole. It was not designed, though, to provide accurate estimates in domains such as states, counties, or school districts – the sample would have to be prohibitively large in order to provide precise estimates of poverty for every county in the USA. These domains are called small areas – the term 'small' does not refer to the size of the area or the population, but to the fact that the sample size in the domain is small or may even be zero.

Consider the states to be the small areas, and let y_k be the proportion of school-age children who are poor in state k. The direct estimate $\bar{y}_k$ of y_k is calculated using data exclusively from the CPS, and $\widehat{V}(\bar{y}_k)$ is an estimate of the variance of $\bar{y}_k$. Since in some states $\widehat{V}(\bar{y}_k)$ is unacceptably large, the current practice for estimating poverty at the state level (see National Research Council, 2000, p. 49) uses auxiliary information from tax returns, food stamp programs, and the decennial census to supplement the data from the CPS. A regression model for predicting y_k using auxiliary information gives predicted values

$$\widehat{y}_k = \widehat{\beta}_0 + \sum_{j=1}^{4} \widehat{\beta}_j x_{jk}$$

where the x_{jk} s represent covariates for state k (e.g., x_{1k} is the proportion of child exemptions reported by families in poverty in state k, and x_{2k} is the proportion of people receiving food stamps in state k). The predicted value $\hat{y}_k$ from the regression equation is combined with the direct estimate $\bar{y}_k$ from the CPS according to the relative amounts of information present in each: the small area estimate for state k is

$$\tilde{y}_k = \gamma_k \bar{y}_k + (1 - \gamma_k)\widehat{y}_k$$

where γ_k is determined by the relative precision of $\bar{y}_k$ and $\hat{y}_k$. If the direct estimate is precise for a state, i.e., $\widehat{V}(\bar{y}_k)$ is small, then γ_k is close to one and the small area estimate $\widetilde{y_k}$ relies mostly on the direct estimate. Conversely, if the CPS contains little information about state k's poverty rate, then γ_k is close to zero and $\widetilde{y_k}$ relies mostly on the predicted value from the regression model.

The small area model allows the estimator for area k to 'borrow strength' from other areas and incorporate auxiliary information from administrative data or other sources. Ghosh and Rao (1994) and Rao (1999) review properties of this model and other models used in small area estimation.

Performing a Model-Based Analysis

The first step in a model-based analysis for either descriptive or analytical use is to propose and fit a model to the data. Dependence among units, such as dependence among children in the same school, can be treated using hierarchical linear models or other methods discussed in Skinner et al. (1989).

The biggest concern in a model-based analysis, as pointed out by Hansen et al. (1983), is that the model may be misspecified. Many, but not all, of the assumptions implicit in a model can be checked using the sample data. Appropriate plots of the data provide some graphical checks of model adequacy and correctness of the assumed variance structure, as described in Lohr (1999). These assumptions can also be partially checked by performing hypothesis tests of nested models, and by fitting alternative models to the data. In the depression example, plotting the data separately for rural and

urban residents would reveal inadequacy of Model 2 relative to Model 1.

Another method that can sometimes detect model inadequacy is comparison of design-based and model-based estimates of model parameters. As mentioned in Sect. 2, if the model is correct for units in the finite population, then the design-based estimates and the model-based estimates should both be consistent for the model parameters. A substantial difference in the estimates could indicate that the sample design contains information not captured in the model, and that perhaps more covariates are needed in the model.

One crucial assumption that cannot be checked using sample data is that the model describes units not n the sample. This assumption is especially important in nonprobability samples and in use of models for nonresponse adjustment or small area estimation.

Models in Survey Design

Kalton (1983) distinguished between the use of models in survey analysis and in survey design, stating that 'the use of models to guide the choice of sample design is well-established and noncontroversial.' In good survey practice, a stratified sampling design is often chosen because it is thought that there are differences among stratum means. An unequal probability design may be employed because of prior belief that large counties have more variability in total number of crime victimizations than small counties; models provide a mechanism for formalizing some of the knowledge about population structure and exploring results of alternative assumptions. Cochran (1977) illustrated the use of models for designing systematic samples. Särndal et al. (1992, Chap. 12) summarized research on optimal survey design, in which auxiliary information about the population is used to select a design that minimizes the anticipated variance of an estimator under the model and design.

Models used for design purposes do not affect the validity of estimates in design-based inference. A poor model adopted while designing a probability sample may lead to larger variance of design-based estimates, but the estimates will retain properties such as unbiasedness under repeated sampling. A good model at the design stage often leads to a design with greatly increased efficiency.

A model-based analysis can be conducted on data from any sample, probability or non-probability. Probability sampling is in theory unnecessary from a pure model-based perspective, and Thompson (1997) and Brewer (1999) concluded that certain forms of purposive non-probability sampling can be superior to probability sampling when a model-based analysis is to be conducted and the model is correct. In practice, however, there is always concern that the assumed model may miss salient features of the population, and probability sampling provides some protection against this concern. For a ratio model, with $Y_i = \beta x_i + \varepsilon_i$ and $V[\varepsilon_i] = \sigma^2 x_i$, the model-based optimal design specifies a purposive sample of the population units with the largest x values. Such a design does not allow an investigator to check whether the model is appropriate for small xs; an unequal probability sample with π_i proportional to x_i does allow such model checking, and allows inferences under either design- or model-based frameworks. As Brewer (1999) pointed out, there is widespread public perception that 'randomized sampling is fair' and that perception provides a powerful argument for using probability sampling for official statistics.

The following sources are useful for further exploration of modes of inference in sample surveys. Lohr (1999, Chap. 11) provides a more detailed heuristic discussion of the role of models in survey sampling; Thompson (1997) gives a more mathematical treatment. The articles by Smith (1994), Rao (1997), and Brewer (1999) contrast inferential philosophies, discuss appropriate use of models in analysis of survey data, and provide additional references.

Sanctions in Political Science

David A Baldwin, Columbia University, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

A sanction is an action by one actor (A) intended to affect the behavior of another actor (B) by enhancing or reducing the values available to B. Influence attempts by A using actual or threatened punishments of B are instances of negative sanctions. Influence attempts by A using actual or promised rewards to B are instances of positive sanctions. Until the mid-twentieth century, sanctions were viewed primarily as mechanisms for enforcing societal norms, including those embedded in laws. Although this normative view of sanctions continues in legal theory, ethics, political theory, and sociology, a broader usage has emerged in political science during the latter part of the twentieth century. This broader usage depicts sanctions as potentially relevant to any type of influence attempt. This usage is typically found in discussions of influence and power. The subfield of political science that has devoted the most attention to sanctions in recent years is international relations and foreign policy. Most of this research has focused on the use of economic sanctions as foreign policy tools. Here, as elsewhere in political science, more attention has been devoted to the negative sanctions than to the positive ones.

A sanction is an action by one actor (A) intended to affect the behavior of another actor (B) by enhancing or reducing the values available to B. Influence attempts by A using actual or threatened punishments of B are instances of negative sanctions. Influence attempts by A using actual or promised rewards to B are instances of positive sanctions. Not all influence attempts involve sanctions. Actor A may influence actor B by reason, for example, or the provision of information without the use of sanctions.

Concepts

Although the definitions of positive and negative sanctions may appear simple, there are both conceptual and empirical difficulties in distinguishing between the two. Some things take the form of positive sanctions, but actually are not; for example, giving a bonus of $100 to an employee who expected a bonus of $500, or promising not to kill a person who never expected to be killed in the first place. Likewise, some things take the form of negative sanctions, but actually are not; for example, a threat to reduce the salary of a person who expected to be fired or the beating of a masochist.

Is withholding a reward ever a punishment? Always a punishment? Is withholding a punishment ever a reward? Always a reward? The answers depend on Actor B's perception of the situation. In order to distinguish rewards from punishments one must establish B's baseline of expectations at the moment when A's influence attempt begins (Blau, 1986). This baseline is defined in terms of B's expected future value position; that is, expectations about B's future position relative to the things B values. Positive sanctions, then, are actual or promised improvements in B's value position relative to B's baseline of expectations, and negative sanctions are actual or threatened deprivations relative to the same baseline.

The determination of B's baseline of expectations is complicated by "prospect theory" (Kahneman and Tversky, 1979). The prospect theory suggests that B is likely to prefer to avoid losses of $100 compared to failure to gain $100 even when the objective probabilities are the same. This psychological tendency must be taken into consideration in estimating B's baseline of expectations.

Historical Context

Although references to both positive and negative sanctions can be traced to the seventeenth century, the most common usage of the term 'sanctions' refers to negative sanctions. Until the mid-twentieth century, sanctions were viewed primarily as mechanisms for enforcing societal norms, including those embodied in laws. Although this normative view of sanctions continues in legal theory, ethics, political theory, and sociology (Barry, 1995; Coleman, 1990; Waldron, 1994), a broader usage has emerged in political science during the latter part of the twentieth century. This broader usage depicts sanctions as potentially relevant to any type of influence attempt, regardless of whether it is aimed at enforcing social norms or not. This usage is typically found in discussions of influence and power (Baldwin, 1971, 1989; Blau, 1986; Oppenheim, 1981; Lasswell and Kaplan, 1950).

Kinds of Sanctions

Because sanctions are defined in terms of the values of the target of an influence attempt (actor B), they may take a variety of forms. Lasswell and Kaplan (1950) identified eight exemplary values that could serve as the basis for positive or negative sanctions: respect, power, wealth, rectitude, physical well-being, affection, skill, and enlightenment.

Although it is sometimes suggested that positive and negative sanctions are opposites in the sense that generalizations about one type are equally applicable to the other, *mutatis mutandis*, this is often not true. Listed below are some of the hypothesized differences between positive and negative sanctions.

A's Burden of Response

When A's influence attempt is based on a promise, B's compliance obligates A to respond with a reward; whereas B's failure to comply calls for no further response from A.

Role of Costs

One important consequence of the asymmetry between positive and negative sanctions is that promises tend to cost more

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93126-X

when they succeed, while threats tend to cost more when they fail (Boulding, 1989; Parsons, 1963; Schelling, 1960). The difference can be summarized as follows: The bigger the threat, the higher the probability of success; the higher the probability of success, the less the probability of having to implement the threat; the less the probability of having to implement the threat, the cheaper it is to make big threats. The bigger the promise, the higher the probability of success; the higher the probability of success, the higher the probability of having to implement the promise; the higher the probability of having to implement the promise, the more expensive it is to make big promises (*ceteris paribus*).

Indicators of Success

While a successful threat requires no action by A, a successful promise obligates A to implement that sanction. In a well-integrated social system, where the probability that B will comply with A's wishes is relatively high, promises will be more visible than threats. Indeed, it is precisely because threats are so successful in domestic politics that they are so difficult to detect. Since most citizens obey most laws most of the time, threats to punish lawbreakers have to be carried out with respect to only a small minority of citizens in most polities.

Efficacy

The question of the relative efficacy of positive versus negative sanctions in exercising influence has been much debated. Parsons (1963) has argued that negative sanctions have more intrinsic effectiveness than positive sanctions in deterrence situations. And ever since Machiavelli and Hobbes, there have been those who argue that force is the ultimate influence technique. Identifying the conditions under which one type of sanction is more effective than another is likely to continue as a focus of research in political science as well as in other social sciences.

Legitimation

It is usually easier to legitimize demands based on positive sanctions than demands based on negative ones. An example is provided by one of the most important social institutions in the world – the institution of private property. Most societies have one set of rules specifying the conditions under which a person may be deprived of property and quite a different set of rules specifying conditions under which one person may augment another person's property.

Foreign Policy Sanctions

Political scientists interested in international relations and foreign policy have devoted a great deal of research to sanctions during the last two decades of the twentieth century. Most of this research has focused on economic sanctions, with comparatively little attention devoted to military, diplomatic, or other noneconomic forms of sanctions. Although progress has occurred with respect to systematic gathering of empirical data (Hufbauer et al., 2007), refinement of concepts (Baldwin, 1985, 2000), and development of theories, social scientific research on the role of sanctions in international relations is still in its infancy.

Methodological Problems

Five methodological problems provide useful foci for future research:

1. *Lack of agreement on terms and concepts*. While some scholars conceive of economic sanctions in terms of mechanisms for making any type of influence attempt (Baldwin, 1985), others define economic sanctions in terms of particular policy goals (Pape, 1997). This lack of agreement on the basic concepts not only impedes debate within the field of foreign policy studies, but is also an obstacle to cross-fertilization between the study of economic sanctions in foreign policy and discussions of other kinds of sanctions in other areas of social science.
2. *Preoccupation with economic sanctions*. Research on economic sanctions has been largely insulated from research on other techniques of statecraft. This insulation sometimes gives the impression that economic sanctions are *sui generis*, rather than treating them as a particular type of statecraft. Although actual or threatened military force is a military sanction, it is also usually viewed as a unique focus of inquiry. In order to understand when and why policy makers use economic sanctions, it is necessary to understand the alternatives from which the policy makers choose. These alternatives include diplomatic, military, and/or verbal sanctions (propaganda). Future research on sanctions might usefully focus on comparative studies of alternative types of sanctions and the conditions under which each type is most likely to be cost-effective.
3. *Neglect of positive sanctions*. Research on sanctions is heavily skewed toward negative sanctions. This is true not only of research by international relations scholars, but also of political science in general. During the last two decades, research on positive sanctions has increased (Davis, 2000; Kahler and Kastner, 2006; Newnham, 2000; Nincic, 2010; Solingen, 2012), but the emphasis is still disproportionately on negative sanctions.
4. *Lack of agreement on criteria of success*. Scholars disagree as to which criteria should be used in measuring the success of economic sanctions. Some consider only the effectiveness of the influence attempt in achieving its goals (Morgan and Schwebach, 1997; Pape, 1997). Others argue that estimates of success should take into consideration the costs of the sanctions to the user, the costs for noncompliance inflicted on the target, the difficulty of the undertaking, and the comparative utility of alternative policy options (Baldwin, 1985, 2000). This lack of agreement on how to conceive of success is not peculiar to the international relations literature. Unlike economics, political science lacks a standardized measure of value in terms of which success can be measured. There is much less agreement among political scientists as to what constitutes political success than there is among economists as to what constitutes economic success (Baldwin, 1989). Developing a set of

agreed-upon criteria of success applicable to noneconomic, as well as economic, sanctions would be a valuable step in sanctions research (Johnson and Tierney, 2006).

5. *Premature generalization*. Research on economic sanctions by international relations scholars frequently leads to premature attempts to specify policy implications. Some scholars, for example, imply that only foolish policy makers would use such policy instruments (Morgan and Schwebach, 1997; Tsebelis, 1990). In order to make judgments as to the wisdom of using economic sanctions in a given situation, however, one would need to know how effective such sanctions were likely to be, with respect to which goals and targets, at what cost, and in comparison with which policy alternatives (Baldwin, 2000). Current research on economic sanctions rarely asks such questions.

Abstract

Michael Sandel, a prominent communitarian philosopher, is famous in his criticism of John Rawls' *A Theory of Justice* and his lively teaching skill demonstrated in the Harvard course 'Justice.' He criticizes Rawls' liberalism for assuming a notion of an unencumbered self, which is not only in tension with his principles of justice, but also denying the human capability of deep evaluation on moral good thus discouraging the public deliberation of morality. By his historical retrieval, Sandel shows how the tradition of civic republicanism has been gradually replaced by liberalism in the American political history. The triumph of liberalism might be due to mass migration, the globalizing economy and the culture of consumerism, in which commodification of nearly everything and the unrestraint use of bioengineering has finally crowded out morality and corrupting human values that are important to republican self-government. In the face of modernity, Sandel calls for reviving civic republicanism with sovereignty diffused into multiplicity of political communities.

Biography

Michael J. Sandel is the son of a record salesman. He grew up at Minneapolis, Minnesota. At the age of 13, he moved with his family to Los Angeles. He studied at Palisades High School and became the president of his senior class in high school in 1971.

He was brought up in a Jewish family, and he also raises his children in a Jewish tradition. For Sandel, religion offers a youth framework for moral investigation and leads them to think about the life beyond materialism, even though his religious viewpoints are not palpable in his writings.

In 1975, he was graduated Phi Beta Kappa from Brandeis University in Massachusetts. While still a university student, he was an intern at the *Houston Chronicle* in Washington, DC and as there was a problem in staffing, he got the chance to cover the Watergate hearings. The experience of being a reporter is so important to him. He almost became a political journalist. Nevertheless, the proximity to those events finally motivated him to move the public debate by doing philosophy.

In 1981, he received a doctorate as a Rhodes Scholar from Balliol College, Oxford. At first, he intended to study welfare economics in Oxford. In the mid-1970s, he went to southern Spain with an economist. They were going to try to develop in a paper an economic model, which could integrate with the concern of equality. Meanwhile, one of his tutors at Oxford, Alan Montefiore, advised him to investigate in theoretical grounding of the political economy, and suggested him to take some philosophical books with him to Spain. He ended up taking four: John Rawls's *A Theory of Justice* (1971, *TJ*), Kant's *Critique of Pure Reason* (1997), Robert Nozick's *Anarchy, State and Utopia* (1974), and Hannah Arendt's *The Human Condition* (1958). He spent the days reading the books and worked with his economist friend on the paper in the evenings. Finally, those philosophical books he read have wrecked the economic project. Sandel thought that the contemporary science of economics has inherited too much from utilitarianism. It was too pessimistic about human nature, conceiving humans as simply bundles of preferences and desires. His reading from Rawls and Kant has offered him a convincing critique of utilitarianism. Nevertheless, Sandel also found an important fault in Rawls' conception of society and human nature. At the time, Sandel met Charles Taylor, a professor in political philosophy in Oxford, who finally became a friend and mentor to Sandel. Taylor encouraged him to develop his critique of Rawls.

In 1982, Sandel's first book, *Liberalism and the Limits of Justice* (*LLJ*), based on his Oxford thesis, was published. This book was a substantial criticism on Rawls' model of liberalism set out in *TJ*. His second book, *Democracy's Discontent: America in Search of a Public Philosophy*, was published in 1996.

In 1980, he has gotten a teaching post at Harvard University as an assistant professor, later as an associate professor in 1983, and, in 1999, was named a Harvard College Professor in a special recognition of his teaching skills. He is currently the Anne T. and Robert M. Bass Professor of Government at Harvard University. He teaches ethics, market and morality, and contemporary political philosophy. His most famous undergraduate course is 'Justice,' which also comes as a book, *Justice: What's the Right Thing to Do?* (2009), and the sourcebook of readings *Justice: A Reader* (2007).

In 1998, he presented the Tanner Lectures on Human Values at Oxford University. In these lectures, he gave an initial formulation of the book *What Money Can't Buy*. In 2009, he delivered the BBC Reith Lectures on 'A New Citizenship' that discussed the vision for what Sandel calls 'A New Politics of the Common Good,' two of the four still dealt with markets and morals.

From 2002 to 2005, Sandel worked for the Bush administration's President's Council on Bioethics, which focused on the issue of cloning at that time. The research formed the basis of another book, *The Case against Perfection: Ethics in the Age of Genetic Engineering*. Sandel's other works include *Public Philosophy: Essays on Morality in Politics*, and articles in scholarly journals, law reviews, and other publications. He has also edited *Liberalism and Its Critics*.

Main Writings

Liberalism and the Limits of Justice

In this book, Sandel argues that Rawls' *TJ*, as a kind of reformulation of deontological liberalism, has failed. Inherited from Kant's philosophy, deontological liberalism upholds the

notion of priority of right over good, which is based on the notion of the autonomous subject. The foundation of deontology is Kant's transcendental argument of a notion of subject, in which the self is antecedent to any particular experience and human conditions. Nevertheless, for Rawls, Kant's disembodied subject is inappropriate to be the determinate principles of justice, or else it cannot be applied to actual human beings in the legislation based on such a subject. Therefore, Rawls attempts to reformulate and preserve Kant's deontological teaching by replacing a "hypothetical choice situation (the original position), characterized by conditions meant to yield a determinate outcome fit for actual human beings" (p. 14).

Sandel's analysis shows that Rawls, in setting the foundation of the primacy of justice, endorses his idea of the original position to satisfy two conflicting requirements. On the one hand, standard of evaluating justice must be prior to the current desires to avoid being contingent; on the other, the foundation comes from a thin theory of the good related to actual human desires rather than totally detached from the real world. However, on the one hand, Sandel criticizes Rawls thin theory of the good for being too thick to satisfy Kantian conception of autonomy. On the other, Rawls' assumption of the subject as mutually disinterested has already provided an assumption of human motivation, which is not universal. For Rawls, the assumption is supposed to offer an empirical precondition to affirm the priority of justice unconditionally. However, Sandel argues, we can imagine cases of more intimate, solidaristic social institution, such as family or religious cultural communities, in which the significance of justice is much less prevailing.

According to Sandel, Rawls' theory includes two conceptions of the self. The first is the self as an unencumbered subject with possession, in which the self is antecedently individuated, and is related to its end by choice but without being detached altogether. The second is the priority of plurality over unity in its relation with others. However, Rawls' two conceptions of the self, Sandel argues, are in conflict with his demands of justice.

First, regarding to his difference principle, Rawls has assumed individuals' natural endowments as common assets, which has to be shared and arranged so that the least advantaged may share in the resources of the fortunate. However, Rawls' such notion of endowment is criticized by Nozick as contradicting to deontological liberalism, which emphasizes the inviolability of individual and distinction between persons; it has neglected the difference among persons. With the assumption of the unencumbered self, Rawls may defend by separating their attributes from the selves, so that even the redistribution of attributes, not the person, does not violate the difference among persons. However, such separation leaves us with a subject taken away all empirically identifiable characteristic that resembles Kantian transcendental self, which Rawls tries to avoid. Indeed, Sandel does not reject Rawls' egalitarian tendency of his theory. Instead, he argues that Rawls can defend his notion of endowment, if he appeals to an intersubjective conception of the self, arguing that those who share in my assets are not understood as 'others,' rather as a 'we,' which implies the existence of community in the constitutive sense. One has to see that he/she is brought up by the community, is part of the community, and completed by the community. In this case, we come to see ourselves, "less as individuated subjects with certain things in common, and more as members of a wider subjectivity, less as 'others' and more as participants in a common identity, be it a family or community or class or people or nation" (p. 143). However, such intersubjective conception of the self is rejected by Rawls' antecedently individuated self assumed in his deontological ethics. Indeed, without the constitutive sense of community, Sandel argues, we also cannot explain why the community as a whole deserves the assets of the successful persons in its province and the benefits that flow from them.

The second conflict is related to Rawls' contractarian argument in which the principles of justice are based on the agreement in the original position. There are two important elements in the original position. The first is choice. The second is the need to resolve conflicting claims among plurality of human subjects. Nevertheless, in the real contract, the resolution of confliction inevitably involves the problem of contingency and conventionalism, so the agreement achieved is never unconditional. For Rawls, the original position can overcome the contingency and conventionalism, because behind the veil of ignorance, different parties are assumed to be similarly situated in all relevant respects, differences of power and knowledge disappear; no one is able to choose on the basis of contingently given attributes, so ideal of autonomy is fulfilled. Any agreement reached in the original position becomes a case of pure procedural justice; and the outcome would therefore be just. However, Sandel questions the validity of these provisions in the original position for the choosers. With the veil of ignorance, everyone is similarly situated. People are guaranteed to reason in the same way. There is no difference in the interests or knowledge and so no basis for bargaining and discussion. In such situation, people are not really free to choose, but to choose under certain constrains with an assumed single correct conception of justice. The assumption of plurality and voluntary is called into question.

Furthermore, in Rawls' theory, the conception of good is determined by the consequence for realization of ends and assessing the relative intensity of agent's needs and desires. Sandel criticizes Rawls' subjectivity for not allowing individuals to have deep evaluation of desires and reflection of their identity because Rawls' subject is antecedently given and barren of constituent traits; there is nothing in the self for reflection, and there is no ground to assess the desirability. So the good is not determined by values, but by one's circumstance and arbitrary desires. Instead, Sandel asserts that our agency is capable of a deeper introspection than merely knowing our needs and desires. Nevertheless, if we want to be able to have a more thoroughgoing reflection, we cannot be wholly unencumbered subjects of possession. Rather, we must be subjects constituted, at least partly, by our central attachments and aspirations, always open to progress and renovation in the light of revised self-understandings. As self-understandings are partly constituted by our belonging community, the deepening of the community will diminished the priority of justice. For Sandel, if utilitarianism fails to take seriously our distinctness, Rawls' justice as fairness fails to take seriously our commonality.

In face of communitarian challenge, Rawls' later proposed the idea of political liberalism, which is political, not metaphysical, in nature, to rescue the priority of the right from

criticisms about the nature of the self. However, Sandel finds such rescue as rendering it vulnerable to other criticisms.

First, when grave moral questions are concerned, it is not always appropriate to bracket those values for political purposes. Sandel gives the example of controversy of abortion, whether fetus is human in the case of abortion is critical to the issues. If Catholic's doctrine is right and the fetus is really human, then abortion is a kind of murder. It is not reasonable to bracket the morality in order to attain political agreement.

Second, the case for the priority of the right over the good in his political liberalism is based on the situation that there exists reasonable pluralism about the good in modern democratic societies. However, the fact of reasonable pluralism also applies to the controversies of justice in democratic societies. If Rawls believes that we can reason about justice, it is unreasonable to reject the deliberation of good in the same way.

Third, political liberalism discourages the kind of public deliberation important to examine the plausibility of competing comprehensive moralities. For Rawls, public deliberation has to be limited by the use of public reason, in which political discourse should not refer to comprehensive moral and religious conceptions. However, Sandel reminds us that the argument for the immediate emancipation of the slaves in the abolitionist movement was based on religious reasons. Insisting on liberal public reason might have great moral cost, if political conception of justice approves toleration of grave moral problems, such as slavery or abortion. It might also have political cost. As we can see, political discourse nowadays is lacking sufficient moral discussion, and becomes increasingly preoccupied with the scandalous, sensational media talk shows. It creates a moral vacuum that opens the way for the fanatical, the prejudiced, and other misguided moralism.

Democracy's Discontent: America in Search of a Public Philosophy

In this book, Sandel contrasts the tradition of civic republicanism with that of procedural liberalism in the US political history. The presentation is organized as the intertwining of philosophical and mostly historical analyses. Philosophically, based on *LLJ*, Sandel continuous his criticism of liberalism and argues for the idea of civic republicanism with the sense of multiply situated selves. Historically, Sandel shows, while both procedural liberalism and civic republicanism used to be present throughout American politics, American political discourse, in the recent decades, has become dominated by procedural liberalism, and has steadily crowded out the republican understandings of citizenship, which is important for self-government.

Sandel's historical retrieval is tracing mainly through development of political economy and constitutional law. In part one, Sandel has discussed the controversies and development of American constitutionalism in the area of religious liberty, free speech, and the regulation of pornography, abortion, homosexuality, and no-fault divorce laws. Throughout the discussion, Sandel shows that while the Constitution is a framework of rights with neutrality among ends, "[w]hat counts as neutrality is often controversial and admits competing interpretations" (p. 50). Underlying these interpretations are different conceptions of what free moral agency consists in. These judgments are therefore not neutral after all. Nevertheless, the republican vision has been steadily replaced by procedural liberalism, which stresses basic individual rights to constrain the majority will. For Sandel, procedural liberalism has implicitly assumed the idea of unencumbered self, which is free to choose their own ends. It fails to respect persons, as member of particular communities to which they belong (p. 89). Such persons are bound by duties derived from religious or traditional belief, that is true for them, but not chosen by themselves (p. 67).

Sandel reminds us that the American Revolution was originally aspiring to generate a new community of common good. By separating from England, Americans attempt to stave off corruption and to realize republican ideals, to "renew the moral spirit that suited Americans to republican government" (p. 127). Unfortunately, in the years following independence, leading politicians and writers started to worry the corruption of the public spirit by the rampant pursuit of luxury and self-interest. Nowadays, most of American practices and institutions have thoroughly embodied the philosophy of procedural liberalism. Despite its philosophical problem, it has offered the public philosophy by which Americans live.

In part two, Sandel has laid out the American history of political economy. Regarding to the debates of large-scale manufacturing in the early republic, it shows the eclipse of Jefferson's vision of the virtue and independence of yeoman farmers. The emergency of factory life raises the controversy of working for a wage and its relation to self-government. The alteration of labor movement and the acceptance of wage labor as a permanent condition lead to the failure of the artisanal republican tradition and the rise of voluntarist conception of freedom. During the Progressive era, there is a contest between the decentralist vision of Louis Brandeis and Woodrow Wilson and the nationalization of big business of Theodore Roosevelt and Herbert Croly on how to preserve democratic self-government in the face of concentrated economic power. However, in the twentieth century, the culture has shifted to the political economy based on consumer identity. Finally, the 'political economy of citizenship' was replaced by the 'political economy of growth and distributive justice' in the Keynesian revolution of Franklin Roosevelt. Throughout these debates, the underlying concern of both sides initially appealed to the consideration of civic character formation, which is most hospitable to self-government (p. 124). Nevertheless, the consequences of these debates have finally excluded the civic consideration from the scope of contemporary American politics. In the last few decades, in particular in the civil rights movement, the procedural republic has won a total victory and the republican tradition has been almost repressed. The predomination of procedural liberalism nevertheless leads to anxiety for "the loss of self-government and the erosion of community" (p. 294).

According to Sandel, the triumph of procedural liberalism could be due to the great wave of migration and the growing diversity of nation. These factors have made the republican character formation of citizens difficult to achieve and strengthened the appeal of moral neutrality. Furthermore, the rise of a national economy and globalization has complicated the republican ideal of subjecting economy to democratic

account. In particular, the culture of consumerism in the capitalist society has offered an individualistic, privatized vision of freedom, which has diminished the aspiration of republican freedom as self-government.

With the loss of community and shared public life necessary to self-government under the aura of procedural liberalism, Sandel calls for an American revival of the republican ideal. Instead of being cosmopolitanism, Sandel suggests to restore politics of self-government, which plays itself out in a multiplicity of political communities in which sovereignty is diffused (p. 345). For Sandel, civic life is best nourished in a particular community, which is intermediate between the individual and the state. Only when sovereignty is scattered and citizenship formed across multiple sites of civic participation can the regime be integrated to rival global market forces, while public life remains to be differentiated, which inspire citizens' reflective allegiance to the whole nation.

What Money Cannot Buy: The Moral Limits of Markets

As the unfettered market and consumerism is one of the great impediments to a politics of civic virtue, Sandel, in this book, explores the relations between market and morality with examples of how we are degrading public life as part of an unrestrained marketization and commodification of almost everything.

From the time of Margaret Thatcher and Ronald Reagan to the financial crisis of 2008, it was an era of what Sandel calls 'market triumphalism' (p. 6). Market was held to be the key to prosperity and freedom. Nearly everything can be priced. Our everyday life has been dominated by market value and thinking. However, Sandel argues throughout this book that market would lead to two problems: inequality and corruption.

The book explores five area of problematic commercialization of our life: (1) paying for the queue; (2) paying for motivating better health, education and environmental protection; (3) commodification of honorary degree, admission of prestigious colleges or universities; (4) commercialization of one's death; and (5) the ubiquity of commercial advertising.

First, for Sandel, allowing payment for queue for certain public service would be unfair to the poor. To turn free public service into market commodity would corrupt the nature of service. Charging admission to congressional hearings, or to allow scalpers to profit from free public performance and religious rituals would violate their original aims, thus degrading their values.

Second, although market power is efficient to motivate certain moral activities, such as reading, health care and environment protection, it indeed induces, Sandel argues, people to do the right things with pervasive incentives. Paying people to be healthy can rebound by failing to cultivate the attitudes of maintaining good health. The monetary incentives of reading books may replace the intrinsic incentives of learning. Economists usually assume that the operation of markets is value-neutral. However, Sandel refutes this assumption, "Markets leave their mark on social norms. Often, market incentives erode or crowd out nonmarket incentives" (p. 64).

Third, if honorary degree or admission of prestigious universities can be sold or bought, it is not only unfair to the poor children, perpetuating social inequality, but also corrupts the institutional integrity. This is because "higher education not only equips students for remunerative jobs, but that it also embodies certain ideals – the pursuit of truth, the promotion of scholarly and scientific excellence, the advancement of humane teaching and learning, the cultivation of civic virtue" (p. 110). Allowing the need of fund-raising to be the most important agenda of college would distort the very reason for existence of university.

Fourth, with the janitors insurance, Sandel shows how life insurance, which originally attempts to diminish the financial impact of death on survivors and dependents, was finally corrupted into a kind of gambling against other people's lives.

Fifth, the commercial advertising nowadays has reached places we would not have ever imagined, such as public transports, schools, classrooms, public area, police cars, fire hydrants, academic books, and human bodies. The culture of commercialization of everything is pernicious to the character building of the youth. The commercial advertisement in the school would further obscure the boundary between places, and makes everywhere a site of selling. While public schools teach students to be discipline and to evaluate their own desire, markets motivate students to pursuit the satisfaction of desires. It violates the ideal of education (p. 200).

All these problems of marketization of almost everything cannot be simply explained in terms of freedom or equality. Sandel argues, in order to identify what trouble us about the current condition, we need the moral terminology of corruption and degradation, which appeals to conceptions of good life (p. 187). The corruption argument also brought to us an important insight that "markets are not mere mechanisms; they embody certain values. And sometimes, market values crowd out non-market norms worth caring about" (p. 113). Our society tends to avoid the deliberation of the conception of good life because of its controversial nature. Such worries impede us to bring our moral conviction in the public area. However, as Sandel states, "shrinking from these questions does not leave them undecided. It simply means that markets will decide them for us. This is the lesson of the last three decades" (p. 202).

The problem of inequality also leads to what Sandel calls "the skyboxification of American life" (p. 203). People from different classes are separated in their living, working, studying, and playing. There is a lack of common good, common life, and sharing of common experience among citizens. It is harmful to social solidarity and democracy. "Democracy does not require perfect equality, but it does require that citizens share a common life. What matters is that people of different backgrounds and social positions encounter one another, and bump up against one another, in the course of ordinary life" (p. 203).

The Case against Perfection: Ethics in the Age of Genetic Engineering

In discussing issues about the idea of eugenics in the era of genetic engineering, such as muscle-enhancement, memory-enhancement, height-enhancement, and reproductive technologies, Sandel shows us the deficiency of fairness argument and autonomy argument. First, even without genetic enhancement, some people are always better endowed than others in competitions, but we never consider it as violating

principle of fairness. Second, even if coercion is absent, eugenics is not therefore vindicated. The autonomy argument cannot elucidate our moral perplex about people who use genetic technology not to cure illnesses, but to extend beyond health, to enhance their abilities so that we are uplifted above the norm. Sandel argues, the way of dealing with the ethics of genetic enhancement is to "questions about the moral status of nature, and about the proper stance of human beings toward the given world" (p. 9). For Sandel, the crucial problem of eugenics and genetic enhancement is that they exemplify "the one-sided triumph of willfulness over giftedness, of dominion over reverence, of molding over beholding" (p. 85). From the religious perspective, to perceive our talents as wholly our own doing is to play God, to confuse our role and the idea of creation. From the aspect of secular philosophy, the idea of the 'self-made man,' represented by bioengineering, would transform our understanding of three values: humility, responsibility, and solidarity (p. 86). To see ourselves as a creature of God or nature is to remind us that we are not fully responsible for our shortcomings. Today, if a basketball player misses a rebound, he/she may be accused of being out of position by his coach. In a world we can master of our genetic endowments, she/he may be accused for being too short. We need to bear a much greater responsibility on our talents and performance in such a manipulating society. If the world is used to specifying genetic traits of their children, the world would also be unfriendly to the unbidden. Therefore, to see children as gift is to learn humility. To accept them as they come rather than products of design teaches parents "to be open to the unbidden" (p. 86). The notion of giftedness also helps to justify redistribution and enhance solidarity. The reason the successful have an obligation to the least-advantaged members of community is that they are not fully deserved for their achievement. Their achievements partly come from the outcome of the genetic lottery. The successful persons are therefore responsible to share their rewards with those who lack those endowments.

His Influence

Sandel's writings are easy to read. His books are well-known globally. His works have been translated into 23 languages. In particular, his *LLJ* has been widely regarded as one of the most important critique of Rawls' *TJ*. Many scholars perceive that Rawls attempts to come to terms with Sandel's criticisms in his *Political Liberalism*, a case for liberalism that is political not metaphysical. Sandel's criticisms have also been extended to the critique of other liberal equalitarian, such as Ronald Dworkin, as well as Robert Nozick, the libertarian. This book has secured his academic reputation in the United States, conceiving him as one of the major proponents of communitarianism, on a par with other communitarians, such as Alasdair MacIntyre, Charles Taylor, and Michael Walzer. This book helped shape the liberal-communitarian debates in the 1980s and 1990s. It has set out the issues of the self and its relation to the community as the clear lines of debate for the theoretical discussion. However, Sandel is resistant to the label 'communitarianism,' because it is usually misunderstood as a kind of majoritarianism.

His second book *Democracy's Discontent* has also provoked lots of responses from both liberals and communitarians. A few years later, *Debating Democracy's Discontent*, the collected responding essays made by political and legal theorists is published. Sandel's thesis of civic republicanism is regarded as helpful guidance to reinvigorate the older philosophical tradition in the modern context (Hall, 2003: p. 113). However, it is also regarded by liberals as risky of being paternalistic and oppressive to individuals. Sandel admits such risk, but he reminds, there are also risks of being moral vacuum by the procedural liberalism, which has "left liberals ill-equipped to engage moral and religious argument in political debate" (Sandel, 1998b: p. 329).

Sandel's lectures are legendary. Up to now, more than 15 000 students have enrolled on his undergraduate course 'Justice,' an introduction to moral and political philosophy. His classes have been filmed by Harvard and WGBH (Boston's PBS station) and produced a public television series that aired across the country in 2009. It is also the first Harvard course to be freely available online and on television. It becomes the hallmark of Harvard philosophy course. In 1985, Sandel was the recipient of the Harvard-Radcliffe Phi Beta Kappa Teaching Prize and honored for excellence in teaching by the American Political Science Association in 2008. His lecturing style is in the form of Socratic dialogue with students debating about moral goods related to different social issues. To certain extent, his lecture can be considered as exemplifying his republican ideal about public moral deliberation.

Sandel has a huge audience not only in the West, but also in Asia. For instance, he has given lectures in mainland China in 2007, Taiwan and Tokyo in 2010, and Seoul in 2012. The Japan Times describes Sandel's visit, "Few philosophers are compared to rock stars or TV celebrities, but that is the kind of popularity Michael Sandel enjoys in Japan." In 2010, China Newsweek named him the 'most influential foreign figure of the year' in China.

Abstract

Edward Sapir studied anthropology under Franz Boas, and became the leading exponent of linguistic anthropology in the first half of the twentieth century. He carried out important work on the descriptive linguistics of North American Indian languages, including definitive studies of Takelma, Southern Paiute, Nootka, and the Athabaskan languages. He was also deeply concerned with exploring historical links among American Indian languages, and made significant contributions to the comparative linguistics of the Uto-Aztecan, Athabaskan, Hokan, and Penutian families. His career until 1925 was almost entirely devoted to this research, but from then until his death he taught at the University of Chicago and at Yale, where he had considerable influence in establishing the paradigm for twentieth-century linguistic research and in training the first generation of American structural linguists. He was also involved deeply in the development of a psychologically sophisticated model of social research, both within anthropology (where he helped create the Personality and Culture school) and in interdisciplinary collaboration, in particular with the psychiatrist Harry Stack Sullivan. A gifted teacher and lucid writer, Sapir was a major intellectual figure in the 1920s and 1930s. His general book, *Language* (1921), was read widely and is still in print.

General Career

Edward Sapir was born in Lauenburg, Germany (now Lebork, Poland) on 26 January 1884, but his family emigrated to the United States when he was 5 years old and eventually settled in New York City. His brilliance earned him a full scholarship to the prestigious Horace Mann School and subsequently a Pulitzer fellowship to Columbia College, where he received his BA in 1904. He continued with graduate work in Germanic philology, but was soon drawn into Franz Boas's orbit and took up an anthropological career, for which he proved extraordinarily well fitted. In 1905 he began a series of field visits to the West that resulted in the detailed documentation of several American Indian languages and cultures, including Wishram Chinook, Takelma, Yana, Southern Paiute, and Nootka. The speed and accuracy with which Sapir collected linguistic and ethnographic data has probably never been surpassed, and his notes, even from his earliest field trips, are among the most valuable manuscripts in American Indian studies.

After receiving his doctorate from Columbia in 1909 with a dissertation on the Takelma language, Sapir taught briefly at the University of Pennsylvania, and in 1910 became Chief of the Division of Anthropology in the Geological Survey of Canada. He remained in this position until 1925, making the Nootka (Nuuchahnulth) language the focus of his research from 1910 to 1914. Between 1915 and 1920, when World War I and its aftermath brought field work to a halt, he devoted a considerable amount of time to the comparative linguistics of North American languages, establishing the Na-Dene relationship between Athabaskan, Tlingit, and Haida, and proposing expansions of the Penutian and Hokan stocks to include a large number of languages in North and Central America. During this period he also began making a name for himself as a literary and social commentator, and began publishing his experimental poetry.

Sapir married Florence Delson in 1911, and they had three children. Shortly after the birth of their third child in 1918, Florence Sapir began to manifest signs of serious illness, partly psychological in character. Although his wife's deteriorating health became a great concern to Sapir, and her death in 1924 was emotionally devastating, he remained committed to the intensive field documentation of American Indian languages, and in 1922 commenced an Athabaskan research program that eventually encompassed fullscale descriptive studies of Sarsi, Kutchin (Gwich'in), Hupa, and Navajo. This work was motivated partly by Sapir's conviction that a historical relationship could be demonstrated between the Na-Dene languages of North America and the Sino-Tibetan languages of East Asia.

After the publication of his highly influential book *Language* (1921) Sapir was regarded widely as one of the leading linguists of his generation. In 1925 he accepted Fay-Cooper Cole's offer of an academic position in the newly reorganized Department of Anthropology and Sociology at the University of Chicago. The move from Ottawa, and his second marriage to Jean McClenaghan, with whom he was to have two more children, was an emotional and intellectual watershed. He found the interdisciplinary atmosphere at Chicago stimulating and increasingly he addressed general and theoretical topics in his professional writing. He also began contributing sprightly and provocative essays on general social and cultural topics to such publications as Mencken's *American Mercury*. While much of his teaching was in linguistics and he took a leading role in establishing that discipline as an autonomous field of study, Sapir also became involved in developing a general model for social science. After he moved to Yale in 1931 as Sterling Professor of Anthropology and Linguistics he became interested particularly in a psychologically realistic paradigm for social research (see Irvine, 1999) and led a seminar on personality and culture. Meanwhile linguistic work on Athabaskan, specifically Navajo, continued to absorb him, and the prospect of finding remote connections of the Na-Dene languages in Asia had led him to the study of Tibetan and Chinese.

This extraordinarily diverse agenda was abruptly suspended in the summer of 1937 when Sapir suffered a serious heart attack, from which he never fully recovered. After a year and

a half of precarious health and restricted activity he died in New Haven, Connecticut on 4 February 1939, a few days after his 55th birthday.

Scientific Contribution

Sapir's scientific work can be divided into three distinct parts. First, there is his substantive work in descriptive and comparative linguistics, almost entirely devoted to North American Indian languages. Second, there is his role in establishing the paradigm for twentieth century linguistic research. Finally, there are the flashes of insight – seldom elaborated into formal hypotheses – with which Sapir from time to time illuminated the landscape of linguistic and social theory.

Substantive Work on Languages

The face that American Indian linguistics presents to the world at the beginning of the twenty-first century probably owes more to Sapir than to any other scholar. When Sapir took up the anthropological study of American Indian languages in 1905, the field was dominated by the classificatory concerns of John Wesley Powell's Bureau of American Ethnology, which saw as its principal task the identification of language and dialect boundaries, and the grouping of languages into families whose historical relationship was undoubted. Only a few earlier scholars like Pickering and Humboldt had been interested in the general philological study of these languages. It was Franz Boas, Sapir's mentor at Columbia, who first proposed making comparative investigation of the grammatical structures of American Indian languages (and of non-European languages generally) a topic for sustained scientific research. Drawing his model from a German tradition of associating language and social behavior that led back through Steinthal to Humboldt, Boas impressed upon his anthropological students the necessity of understanding how linguistic 'morphology' (by which he meant grammatical structure) channeled ideas into expressive forms. Unfortunately for Boas, few of his students were equipped either by training or by intellectual inclination to carry out linguistic research of a more than superficial kind.

The only significant exception was Sapir, whom one may imagine was attracted to Boas's anthropology for precisely this reason. From his earliest fieldwork on Wishram Chinook in 1905, Sapir made grammatical analysis the centerpiece of his research, and from his first publications portrayed American Indian languages with a descriptive clarity they had seldom before enjoyed. His accomplishments are legendary to the scholars who today study these languages, and must rank in the first tier of the grammarian's art. The most renowned of his published studies include a full grammar of Takelma, a now-extinct language of southern Oregon (1922); a full grammar and dictionary of Southern Paiute (1930–31/1992); and an outline grammar of Nootka, with texts and vocabulary, prepared with the assistance of Swadesh (1939).

Sapir's grammatical descriptions are couched in a metalanguage derived from European comparative philology, tempered by Boas's insistence that the structure of every language is *sui generis*. In discussions of the evolution of grammatical theory, Sapir's grammars are sometimes portrayed as 'processual' or as early examples of 'generative' descriptions, but such labels imply a theoretical deliberation that was uncharacteristic of Sapir's work. His concern was to explicate the patterns of the language under consideration as lucidly and unambiguously as possible, not to test a general theory of linguistic structure.

The aptness with which Sapir's descriptions captured the spirit of the languages he analyzed is no better illustrated than by his model of Athabaskan grammar. Although in this case it was not embodied in a full grammatical treatment, he laid out the basic features of his descriptive system for Athabaskan in a number of shorter works, and passed it on to his students and successors through his teaching and in his files. Sixty years after his death it remains the standard descriptive model for all work in Athabaskan linguistics, regardless of the theoretical stance of the analyst.

Throughout his career Sapir maintained a deep interest in historical relationships among languages. He took pride in extending the rigor of the reconstructive method to American Indian language families, and laid the foundations for the comparative study of both Uto-Aztecan and Athabaskan. In the 1930s he returned to Indo-European linguistics and made major contributions to the Laryngeal Hypothesis (the proposal, originating with Ferdinand de Saussure, that the phonology of Proto-Indo-European included one or more laryngeal or pharyngeal consonants not attested in the extant Indo-European languages).

The Professionalization of American Linguistics

By 1921, Sapir was able to draw on the analytic details of the American Indian languages on which he had worked to illustrate, in his book *Language*, the wide variety of grammatical structures represented in human speech. One of the most significant impacts of this highly successful book was to provide a model for the professionalization of academic linguistics in the US during the 1920s and early 1930s.

Under Sapir's guidance, a distinctive American School of linguistics arose, focused on the empirical documentation of language, primarily in field situations. Although most of the students Sapir himself trained at Chicago and Yale worked largely if not exclusively on American Indian languages, the methods that were developed were transferable to other languages. In the mid-1930s Sapir directed a project to analyze English, and during World War II many of Sapir's former students were recruited to use linguistic methods to develop teaching materials for such strategically important languages as Thai, Burmese, Mandarin, and Russian.

A distinction is sometimes drawn between the prewar generation of American linguists – dominated by Sapir and his students and emphasizing holistic descriptions of American Indian languages – and the immediate postwar generation, whose more rigid and focused formal methods were codified by Leonard Bloomfield and others. Since many of the major figures of 'Bloomfieldian' linguistics were Sapir's students, this distinction is somewhat artificial, and a single American Structuralist tradition can be identified extending from the late 1920s through 1960 (Hymes and Fought, 1981). There is little doubt that Sapir's influence on this tradition was decisive.

Theoretical Insights

From his earliest work under Boas, Sapir's independent intellectual style often carried him well beyond the bounds of the academic paradigm he was ostensibly working within. He was not, however, a programmatic thinker, and his groundbreaking work, while deeply admired by his students and colleagues, seldom resulted in significant institutional changes, at least in the short term. The cliché 'ahead of his time' is especially apt in Sapir's case, and the influence of some of his views continues to be felt.

This is most striking in structural linguistics, where Sapir must certainly be accounted one of the most influential figures of the twentieth century. As early as 1910 Sapir was commenting on the importance of formal patterning in phonology, and in the 1920s he was among the first to enunciate the 'phonemic principle' which later figured importantly in his teaching at Chicago and Yale. Characteristically, he left it to his students and such colleagues as Leonard Bloomfield to formalize an analytic methodology, while he himself pursued the psychological implications of formal patterning.

Sapir's (1917) trenchant critique of the culture concept, particularly as defined by A. L. Kroeber, was largely ignored at the time. Sapir argued that the attribution of cultural patterning to an emergent 'superorganic' collective consciousness was an intellectual dead-end, and that research would be better directed at understanding the individual psychology of collective patterned behavior. While Kroeber's view was undoubtedly the dominant one in anthropology and general social science for much of the twentieth century, Sapir's analysis is much more consistent with recent models of human sociocultural behavior that have been developed by evolutionary psychologists. The fact that Sapir's views came from someone with extraordinary insight into the elaborate self-referential patterns of language – traditionally, the most formalized and objectified of social behaviors – can hardly be accidental, and again is consistent with recent developments in cognitive science.

In the late 1920s Sapir found an important intellectual ally in Harry Stack Sullivan, a psychiatrist whose interpersonal theory of the genesis of schizophrenia resonated with Sapir's views (Perry, 1982). The two became close friends, and together with Harold Lasswell they planned and organized the William Alanson White Psychiatric Foundation, a research and teaching institution that ultimately was located in Washington, DC. In the year before he died Sapir gave serious consideration to leaving Yale and working with Sullivan in a research position at the Foundation.

Sapir's views on the history of language were linked to his view of the abstraction of patterns, and were equally controversial or misunderstood. A distinction must be drawn between Sapir's work, noted earlier, as a historical linguist within a family of languages whose relationship was secure (Athabaskan, Uto-Aztecan, Indo-European), and his explorations of much less certain relationships (Hokan, Penutian, Na-Dene) and possible interhemispheric connections (Sino-Dene). In the former, Sapir worked – with characteristic creativity and insight – with tools and models derived from a long tradition of comparative linguistics. In the latter, it was (or seemed to his contemporaries) often a matter of brilliant intuition. In fact, in this work he usually relied on an assessment of similarities in structural pattern that distinguished features susceptible to unconscious change from generation to generation (e.g., regular inflectional patterns, words) from those that are largely inaccessible to individual cognition. Although he never offered a theoretical explication, his idea of what constituted 'deep' linguistic patterns was exemplified in his classification of North and Central American Indian languages (1929). This classification, which remains influential, is still untested in its own terms.

Impact and Current Importance

A charismatic teacher, Sapir had a succession of highly motivated students both at Chicago and at Yale, the most prominent among them Morris Swadesh (who collaborated with him on Nootka research), Harry Hoijer (who codified Sapir's analysis of Athabaskan grammar), Mary R. Haas, Stanley Newman, C. F. Voegelin, George L. Trager, Zellig Harris, David G. Mandelbaum, and Benjamin L. Whorf. Through these students Sapir exercised a considerable posthumous influence on intellectual and institutional developments in both linguistics and in anthropology through the 1960s. A postwar collection of Sapir's most important general papers, edited by Mandelbaum (1949), was widely read and is still consulted. Harris' (1951) extended review of this book provides a comprehensive summary of Sapir's *oeuvre* as it was understood by his immediate circle.

Sapir is cited most frequently today for the 'Sapir-Whorf Hypothesis' of linguistic relativity, a name that inaccurately implies an intellectual collaboration between Sapir and his Yale student, Benjamin Whorf, who himself died in 1941. The more correctly designated 'Whorf theory complex' (Lee, 1996) was a retrospective construct that derived largely from writings of Whorf's that were unpublished at the time of Sapir's death. Although undoubtedly stimulated by Sapir's writing and teaching, Whorf's proposal that the structure of a language to some extent determines the cognitive and behavioral habits of its speakers cannot be connected directly with Sapir's mature thought on the psychology of language and culture.

Sapir's most enduring achievement is his own descriptive linguistic work. Long after the writings of most of his contemporaries have been forgotten, Sapir's grammatical studies continue to be held in the highest esteem. In recent years his holistic analytic technique has been emulated by a number of linguists seeking an alternative to narrow formalism, particularly when working with American Indian or other indigenous languages.

Sapir's life and work was the subject of a 1984 conference (Cowan et al., 1986), from which emerged a plan to publish a standard edition of all of Sapir's work, including edited versions of unfinished manuscripts; by year 2000 seven volumes had appeared. A biography by Darnell (1990) is useful for the externals of Sapir's career, but her reluctance to give an intellectual account of Sapir's work, particularly in linguistics, leaves some important issues still to be addressed (Silverstein, 1991).

Abstract

The Sapir–Whorf hypothesis, also known as the linguistic relativity hypothesis, refers to the proposal that the particular language one speaks influences the way one thinks about reality. Linguistic relativity stands in close relation to semiotic-level concerns with the general relation of language and thought, and to discourse-level concerns with how patterns of language use in cultural context can affect thought. Linguistic relativity is distinguished both from simple linguistic diversity and from strict linguistic determinism. The long history of the hypothesis is sketched with an emphasis on the hierarchical formulations characteristic of most early efforts. This is followed by a description of the work of Sapir and Whorf which departs markedly from this earlier tradition and has been influential in the contemporary period, hence the association of their names with the issue. Whorf's basic argument about analogical influences is outlined in some detail. Despite widespread interest, quality empirical research has been in short supply. Recent efforts to remedy this are described. The research is divided into structure-centered, domain-centered, and behavior-centered types, depending on their manner of approaching the problem. The contemporary period has seen a rapid improvement in the quality of some of these efforts. Current trends likely to characterize future research are briefly characterized.

Nature and Scope of the Hypothesis

The Sapir–Whorf hypothesis, also known as the linguistic relativity hypothesis, refers to the proposal that the particular language one speaks influences the way one thinks about reality. Although proposals concerning linguistic relativity have long been debated, American linguists Edward Sapir (1884–1939) and Benjamin Lee Whorf (1897–1941) advanced particularly influential formulations during the second quarter of the twentieth century, and the topic has since become associated with their names. The linguistic relativity hypothesis focuses on structural differences among natural languages such as Hopi, Chinese, and English, and asks whether the classifications of reality implicit in such structures affect our thinking about reality more generally.

Analytically, linguistic relativity as an issue stands between two others: a semiotic-level concern with how speaking any natural language whatsoever might influence the general potential for human thinking (i.e., the general role of natural language in the evolution or development of human intellectual functioning), and a functional- or discourse-level concern with how using any given language code in a particular way might influence thinking (i.e., the impact of special discursive practices such as schooling and literacy on formal thought). Although analytically distinct, the three issues are intimately related in both theory and practice. For example, claims about linguistic relativity depend on understanding the general psychological mechanisms linking language to thinking, and on understanding the diverse uses of speech in discourse to accomplish acts of descriptive reference. Hence, the relation of particular linguistic structures to patterns of thinking forms only one part of the broader array of questions about the significance of language for thought.

Proposals of linguistic relativity necessarily develop two linked claims among the key terms of the hypothesis (i.e., language, thought, and reality). First, languages differ significantly in their *interpretations* of experienced reality – both what they select for representation and how they arrange it. Second, language interpretations have *influences* on thought about reality more generally – whether at the individual or cultural level. Claims for linguistic relativity thus require both articulating the contrasting interpretations of reality latent in the structures of different languages, and assessing their broader influences on, or relationships to, the cognitive interpretation of reality.

Simple demonstrations of *linguistic diversity* are sometimes mistakenly regarded as sufficient in themselves to prove linguistic relativity, but they cannot in themselves show that the language differences affect thought more generally. (Much confusion arises in this regard because of the practice in linguistics of describing the meaningful significance of individual elements in a language as 'relative to' the grammatical system as a whole. But this latter relativity of the meaning of linguistic elements to the encompassing linguistic structure should be distinguished from broader claims for a relativity of thought more generally to the form of the speaker's language.) A variety of other arguments to the effect that distinctive perceptual or cognitive skills are required to produce and comprehend different languages likewise usually fail to establish any general effects on thought (see Niemeier and Dirven, 2000).

Linguistic relativity proposals are sometimes characterized as equivalent to *linguistic determinism*, that is the view that all thought is strictly determined by language. Such characterizations of the language–thought linkage bear little resemblance to the proposals of Sapir or Whorf, who spoke in more general terms about language influencing habitual patterns of thought, especially at the conceptual level. Indeed, no serious scholar working on the linguistic relativity problem as such has subscribed to a strict determinism. (There are, of course, some who simply equate language and thought, but under this assumption of identity, the question of influence or determinism is no longer relevant.) Between the patent linguistic diversity that nearly everyone agrees exists and a claim of

linguistic determinism that no one actually espouses, lies the proposal of linguistic relativity, that is the proposal that our thought may in some way be taken as relative to the language spoken.

Historical Development of the Hypothesis

Interest in the intellectual significance of the diversity of language categories has deep roots in the European tradition (Aarsleff, 1988; Werlen, 1989; Koerner, 1992). Formulations related to contemporary ones appear during the Enlightenment period in the UK (Locke), France (Condillac, Diderot), and Germany (Hamman, Herder). They are stimulated variously by opposition to the universal grammarians, by concerns about the reliability of language-based knowledge, and by practical efforts to consolidate national identities and cope with colonial expansion. Most of this work construes the differences among languages in terms of a hierarchical scheme of adequacy with respect to reality, to reason, or to both. Later, nineteenth-century work in Germany by Humboldt and in France/Switzerland by Saussure drew heavily on this earlier tradition and set the stage for the approaches of Sapir and Whorf. Humboldt's arguments, in particular, are often regarded as anticipating the Sapir–Whorf approach. He argued for a linguistic relativity according to the formal processes used by a language (e.g., inflection, agglutination, etc.). Ultimately this remains a hierarchical relativity in which certain language types (i.e., European inflectional ones) are viewed as more adequate vehicles of thought and civilization – a view distinctly at odds with what is to follow.

Working within the US anthropological tradition of Franz Boas and stimulated by the diversity and complexity of Native American languages, Edward Sapir (1949) and Benjamin Lee Whorf (1956) reinvigorated and reoriented investigation of linguistic relativity in several ways (Lucy, 1992a; Lee, 1997). First, they advocated intensive first-hand scientific investigation of exotic languages; second, they focused on structures of meaning, rather than on formal grammatical process such as inflection; and third, they approached these languages within a framework of egalitarian regard. Although not always well understood, theirs is the tradition of linguistic relativity most widely known and debated today. Whorf's writings, in particular, form the canonical starting point for all subsequent discussion.

Whorf proposed a specific mechanism for how language influences thought, sought empirical evidence for language effects, and articulated the reflexive implications of linguistic relativity for scholarly thought itself. In his view, each language refers to an infinite variety of experiences with a finite array of formal categories (both lexical and grammatical) by grouping experiences together as analogically 'the same' for the purposes of speech. The categories in a language also interrelate in a coherent way, reinforcing and complementing one another, so as to constitute an overall interpretation of experience. These linguistic classifications vary considerably across languages not only in the basic distinctions they recognize but also in the assemblage of these categories into a coherent system of reference. Thus the system of categories which each language provides to its speakers is not a common, universal system, but a particular 'fashion of speaking.'

Whorf argued that these linguistic structures influence habitual thought by serving as a guide to the interpretation of experience. Speakers tend to assume that the categories and distinctions of their language are entirely natural and given by external reality, and thus can be used as a guide to it. When speakers attempt to interpret an experience in terms of a category available in their language, they unwittingly involve other language-specific meanings implicit in that particular category and in the overall configuration of categories in which it is embedded. In Whorf's view language does not blind speakers to some obvious reality, but rather it suggests associations which are not necessarily entailed by experience. Because language is such a pervasive and transparent aspect of behavior, speakers do not understand that the associations they 'see' are from language, but rather assume that they are 'in' the external situation and patently obvious to all. In the absence of another language (natural or artificial) with which to talk about experience, speakers will not be able to recognize the conventional nature of their linguistically based understandings. Whorf argues that by influencing everyday habitual thought in this way, language can come to influence cultural institutions generally, including philosophical and scientific activity.

In his empirical research Whorf showed that the Hopi and English languages treat 'time' differently, and that this difference corresponds to distinct cultural orientations toward temporal notions. Specifically, Whorf argued that speakers of English treat cyclic experiences of various sorts (e.g., the passage of a day or a year) in the same grammatical frame used for ordinary object nouns. Thus, English speakers are led to treat these cycles as object-like in that they can be measured and counted just like tangible objects. English also treats objects as if they each have a form and a substance. Since the cyclic words get put into this object frame, English speakers are led to ask what is the substance associated with the forms *a day*, *a year*, and so forth. Whorf argues that our global, abstract notion of 'time' as a continuous, homogeneous, formless something can be seen to arise to fill in the blank in this linguistic analogy. The Hopi, by contrast, do not treat these cycles as objects but as recurrent events. Thus, although they have, as Whorf acknowledged, words for what English speakers would recognize as temporal cycles (e.g., days, years, etc.), the formal analogical structuration of these terms in their grammar does not give rise to the abstract notion of 'time' that English speakers have. (Ironically, critics of Whorf's Hopi data often miss his point about structural analogy and focus narrowly on individual lexical items.) Finally, grouping referents and concepts as formally 'the same' for the purposes of speech has led speakers to group those referents and concepts as substantively 'the same' for action generally, as evidenced by related cultural patterns of belief and behavior he describes.

Empirical Research on the Hypothesis

Although the Sapir–Whorf proposal has had wide impact on thinking in the humanities and social sciences, it has not been extensively investigated empirically. Indeed, some believe it is too difficult, if not impossible in principle, to investigate.

Further, a good deal of the empirical work that was first developed was quite narrowly confined to attacking Whorf's analyses, documenting particular cases of language diversity, or exploring the implications in domains such as color terms that represent somewhat marginal aspects of language structure. In large part, therefore, acceptance or rejection of the proposal for many years depended more on personal and professional predilections than on solid evidence. Nonetheless, a variety of modern initiatives have stimulated renewed interest in mounting empirical assessments of the hypothesis.

Contemporary empirical efforts can be classed into three broad types, depending on which of the three key terms in the hypothesis they take as their point of departure: language, reality, or thought (Lucy, 1997).

A *structure-centered approach* begins with an observed difference between languages, elaborates the interpretations of reality implicit in them, and then seeks evidence for their influence on thought. The approach remains open to unexpected interpretations of reality but often has difficulty establishing a neutral basis for comparison. The classic example of a language-centered approach is Whorf's pioneering comparison of Hopi and English described above. The most extensive contemporary effort to extend and improve the comparative fundamentals in a structure-centered approach has sought to establish a relation between variations in grammatical number marking and attentiveness to number and shape (Lucy, 1992b). This research remedies some of the traditional difficulties of structure-centered approaches by framing the linguistic analysis typologically so as to enhance comparison, and by supplementing ethnographic observation with a rigorous assessment of individual thought. This then makes possible the realization of the benefits of the structure-centered approach: placing the languages at issue on an equal footing, exploring semantically significant lexical and grammatical patterns, and developing connections to interrelated semantic patterns in each language.

A *domain-centered approach* begins with a domain of experienced reality, typically characterized independently of language(s), and asks how various languages select from, encode, and organize it. Typically, speakers of different languages are asked to refer to 'the same' materials or situations so the different linguistic construals become clear. The approach facilitates controlled comparison, but often at the expense of regimenting the linguistic data rather narrowly. The classic example of this approach, developed by Roger Brown and Eric Lenneberg in the 1950s, showed that some colors are more lexically encodable than others, and that more codable colors are remembered better. This line of research was later extended by Brent Berlin, Paul Kay, and their colleagues, but to argue instead that there are cross-linguistic *universals* in the encoding of the color domain such that a small number of 'basic' color terms emerge in languages as a function of biological constraints. Although this research has been widely accepted as evidence against the validity of linguistic relativity hypothesis, it actually deals largely with constraints on linguistic diversity rather than with relativity as such. Subsequent research has challenged Berlin and Kay's universal semantic claim, and shown that different color-term systems do in fact influence color categorization and memory. (For discussions and references, see Lucy, 1992a; Hardin and Maffi, 1997; Roberson et al., 2000.) The most successful effort to improve the quality of the linguistic comparison in a domain-centered approach has sought to show cognitive differences in the spatial domain between languages favoring the use of body coordinates to describe arrangements of objects (e.g., 'the man is left of the tree') and those favoring systems anchored in cardinal direction terms or topographic features (e.g., 'the man is east/uphill of the tree') (Pederson et al., 1998; Levinson, 2003). This research on space remedies some of the traditional difficulties of domain-centered approaches by developing a more rigorous and substantive linguistic analysis to complement the ready comparisons facilitated by this approach.

A *behavior-centered approach* begins with a marked difference in behavior which the researcher comes to believe has its roots in and provides evidence for a pattern of thought arising from language practices. The behavior at issue typically has clear practical consequences (either for theory or for native speakers), but since the research does not begin with an intent to address the linguistic relativity question, the theoretical and empirical analyses of language and reality are often weakly developed. The most famous example of a behavior-centered approach is the effort to account for differences in Chinese and English speakers' facility with counterfactual or hypothetical reasoning by reference to the marking of counterfactuals in the two languages (Bloom, 1981). The interpretation of these results remains controversial (Lucy, 1992a).

Future Prospects

Two research trends are unfolding at the present time. First, in the cognitive and psychological sciences awareness is increasing of the nature and scope of language differences. This has led to a greater number of studies focused on the possible cognitive consequences of such differences (e.g., Levinson, 2003; Niemeier and Dirven, 2000). Second, an increasing integration is emerging among the three levels of language and thought problem (i.e., the semiotic, structural, and functional levels). On the semiotic side, for example, research on the relationship between language and thought in development is increasingly informing and informed by work on linguistic relativity (Bowerman and Levinson, 2001). On the functional side, research on the relationship of cultural and discursive patterns of use is increasingly being brought into dialogue with Whorfian issues (Silverstein, 1979; Friedrich, 1986; Wierzbicka, 1992; Hill and Mannheim, 1992; Gumperz and Levinson, 1996).

The continued relevance of the linguistic relativity issue seems assured by the same impulses found historically: the patent relevance of language to human sociality and intellect, the reflexive concern with the role of language in scholarly practice, and the practical encounter with linguistic diversity. To this we must add the increasing concern with the unknown implications for human thought of the impending loss of many if not most of the world's languages (Fishman, 1982).

Abstract

Writer, thinker, educator, and politician, Domingo Faustino Sarmiento (1811–88) was one of the great intellectual figures of Argentinian culture in the nineteenth century. He was born in a poor family, but Sarmiento, who attended just a few years of elementary school, became a career educator and man of letters. He wrote his best books in exile, where he had been thrown by the civil war that divided the country. His thesis on the South American caudillo (military leaders) particularly his famous reflection on Argentinian political life in *Facundo* had great influence in Latin America. Sarmiento ruled Argentina between 1868 and 1874.

Biography

Domingo Faustino Sarmiento was one of the great figures of the Argentinian intellectual elite of the nineteenth century. Sarmiento was a liberal writer and thinker and his work reflects the development of social and political concerns that were partly his own but also shared with the generation of which he was a part (Bunkley, 1952).

After the War of Independence against Spain and the ensuing political and social dislocation that produced the 1810 revolution, Argentina, like the majority of Latin American countries, sank into a long crisis, with various stretches of bloody turf war (war). Finding a way out of this crisis was precisely the central concern of the so-called 'generation of 1837,' which introduced literary and social Romanticism to the country (Weinberg, 1958). The program of this small, young intelligentsia was based on the premise that the study of local reality and customs was required to establish an adequate political order reflecting national aspirations (i.e., a legitimately Argentinian political order). According to this 'Romantic generation,' understanding the nature of South American history was necessary to understand the hegemony of the *caudillos* (military leaders that ruled most of Latin America in this era) and to comprehend the failure of even enlightened governments to evolve political institutions suitable for the national progress. The circle, composed mostly of university students, first met in a club, the Literary Salon, established in 1837 in Buenos Aires, and soon after, they met in a secret lodge: the Association of the Young Generation of Argentina. The lodge was short-lived, but from the founders and supporters of the ideological project of 1837, a liberal constitutional doctrine would proceed, along with the emergence of a national historiography and guidance for research on the literary past that would impose itself in the second half of the nineteenth century (Romero, 2001). One of the names associated with this intellectual program is that of Domingo Faustino Sarmiento.

Sarmiento was born in 1811 in a secluded corner of Argentina, in the city of San Juan, the capital of San Juan Province. His parents were *decente* (poor but respectable and considered white – i.e., with no Indian or African blood). From infancy, Sarmiento knew the tribulations of a life of destitution in a home that depended on maternal work. The nine years he attended the *Escuelas de la Patria* (Schools of the Homeland) provided his only formal education. Sarmiento would recall later that he also received lessons from his priest uncles, whose teachings of religion, Latin, geography, and grammar extended far beyond his initial childhood training. From these familial lectures, he obtained a love of reading, a passion for books, a yearning for knowledge, and the passion for educational action. Given the outstanding skills that the child showed in his studies, his parents imagined that his education and knowledge would provide him a role and a reputation in the public life of the country (Anderson Imbert, 1960).

But this was not an easy road in a country torn with civil war (Halperin Donghi, 1972). In effect, nineteenth-century Argentina was divided into two irreconcilable factions: the *unitarios*, who had their moment in the spotlight under the enlightened rule of Bernardino Rivadavia; and the *federales*, who had defeated the *unitarios* and aligned themselves with the provincial *caudillos* and their popular rural and urban base. Since 1835, the most powerful of these *caudillos*, Juan Manuel de Rosas, ruled the province of Buenos Aires with an iron fist and, with the most important of the provinces as his base, also ruled the Argentinian Confederacy almost continuously from 1829 to 1852. (The Argentine Confederacy was the official name of a political network of agreements and commitments between Rosas and the leaders of the other provinces.)

Although the Sarmiento family had been on the federal side, Sarmiento himself took up arms and joined the *unitario* cause, the faction supported by the majority of the country's intellectual elite. Sarmiento was still an adolescent when he enrolled with the *unitarios* and participated in some of the skirmishes of the civil war that dominated political life in Argentina at that time. The troops he had joined were defeated and that led to his imprisonment and subsequent exile in neighboring Chile. He returned to his province the following year, but because of military setbacks, he had to go into exile in Chile again, where he remained from 1831 to 1836 (Gálvez, 1945).

In 1836 Sarmiento returned to San Juan, where a federal leader governed with a more benign and tolerant style. There he would found a school for women and a newspaper, *El Zonda*. He also reorganized a theatrical association and began to write. More importantly for his ideological evolution is the discovery he made between 1838 and 1840 of a new set of doctrines derived from the European thinking of that time. A young

lawyer from San Juan, who had been a member of the Romantic ideological in Buenos Aires, carried to San Juan not only the ideas of that circle, but also his personal library. Through his friend's library, the voracious self-taught Sarmiento read books and magazines that spread the doctrine of the Romantic movement in France. This literature mixed the philosophy of history with historical studies, philosophical eclecticism and the critique of eclecticism, social humanitarianism and liberalism, literary theories with theories of the law. The authors and titles that would evoke quotes years later from this time of discovery were Guizot, Chateaubriand, Lammenais, Madame de Stäel, Pierre Leroux, Quinet, Lerminier, together with the French journals *La Revue des Deux Mondes* y *La Revue Enciclopédique*. Significantly for Sarmiento, de Tocqueville's *Democracy in America* became an intellectual guide, as it was to the rest of his generation. When in 1840 an argument with the federal *caudillo* that governed San Juan forced him to take exile again, he took with him to Chile this new wealth of readings and ideas (Botana, 1984).

Sarmiento soon became a prominent personage in Chile, where he counted on the protection of Manuel Montt, a leading figure in the Chilean government's conservative party (Galvez, 1945). Access to the press was the first step in his remarkable public career. Through journalism, he soon revealed his talent for prose about combat, the literature of ideas, and the chronicling of customs. He threw everything he had read into his articles, sometimes in a rather jumbled way. He also began to test the biographical genre, and in a short text evocative of an Argentinian *caudillo*, Sarmiento showed his narrative ability through the story of Félix Aldao. His second biography appeared as a series in the newspaper he directed and led to his fame as a writer and man of ideas: Civilization and barbarism, the life of Facundo Quiroga; and physical aspects, customs and habits of the Republic of Argentina, published in 1845 and known simply as *Facundo*. This same year, Minister Montt charged him with the task of studying *in situ* the operation of primary education in Europe and the United States. The commission was not unjustified, since education was another area where Sarmiento excelled in Chile; indeed, in 1842 he had been appointed Director of the Normal School of Primary Instruction and, 2 years later, wrote a *Method of Gradual Reading* that would be adopted in all primary schools in the country. This background, along with other instructional works, testified to the passionate commitment of the Argentinian writer to public education, which he saw as an instrument of modernization and democratization for all the societies of South America (Verdevoye, 1963).

During his long second exile in Chile, and at the behest of the Chilean government, Sarmiento traveled widely throughout South America, Europe, and the United States, the fruits of which were his books *Popular Education* and *Travels*, both published in Chile in 1849. When the end of the Rosas government seemed near, Sarmiento produced a proposed reorganization of his country, *Argirópolis*, and also wrote his celebrated autobiography, *Memories of Provincial Life*, a book that his rivals saw as the opening of a campaign for the Presidency of Argentina. He left exile in 1851 to participate in the struggle against Rosas but soon returned to Chile because, in his view, the *caudillos* continued to rule even though Rosas was no longer in power. Finally, in 1855 he returned to Argentina and settled in Buenos Aires, then a separate state of the national political order. In Buenos Aires, Sarmiento began his career in public office: municipal adviser, repeatedly a senator, government minister, governor of San Juan for 2 years, and the head of numerous diplomatic missions. While serving as ambassador to the United States, many leaders and officials of the Army offered him the candidacy for president of the republic in the elections to be held in 1868. Sarmiento agreed, was elected and maintained executive power for 6 years – years marked by a war with neighboring Paraguay and various episodes of struggle between internal factions.

Once he completed his work as president, he returned to his two passions, public education and preaching through media. Now that he was a marginal player in politics, a continuing controversy surrounding the law of common education offered Sarmiento, the chance to return to battling for what he deemed essential for the civilization and progress of his country – universal education (Weinberg, 1984). The time of writing great books was over; his most significant works were produced when he was exiled in Chile. His most ambitious post-Presidential intellectual project, *Conflict and Harmonies of the Races in America* (1883), paid tribute to the racism of positivist sociology in that era, but it was an unsuccessful work. At the time of his death in 1888, Argentina had changed dramatically because of the enormous drive that Sarmiento had for the education of his country (among other reasons, of course).

The Literary Legacy of Sarmiento

Sarmiento was the premier Argentinian author of the nineteenth century. Almost all of his written work is compiled in the collection organized by Luis Montt and Augusto Belin, *Works of D.F. Sarmiento*. Much of the 52 volumes of work reflect Sarmiento's journalistic labors, much of which comprise some of the best writings that his pen produced. The Argentinian writer Eduardo Mallea collected some of the literary articles and documented social habits from Sarmiento under the title *Prose of Seeing and Thinking* (Sarmiento, 1943). These writings showcase an almost wild and vivid talent for uniting with his subjects, an animated and personal prose style, an alert and thoughtful vision, acute observation of the curious and the quaint and ensuing generalization about the habits of men, and most of all the values Sarmiento preached to achieve progress throughout South America. There are also complaints and quarrels in these pages, reflections of an author who felt at home amid controversy. In many of the debates waged in the press, as in the discussion of Romanticism or about the orthography of Spanish, Sarmiento revealed himself to be a skilled intellectual fighter.

There is scholarly consensus that Sarmiento's most successful works are those composed during the years he was exiled in Chile. There are three works that cement his fame as a writer and have confirmed their place as national literary classics: *Facundo*, *Travels*, and *Memories of Provincial Life*. None of these shows a master plan or unity of structure. It is, rather, the mix of styles and subjects that distinguishes and inspires his discourse. If we put aside *Facundo*, to which we will return, the second of these works, whose complete title is *Travels through Europe, Africa and America* (1845–47), shows almost naturally,

through the very genre chosen to express his thoughts, the functioning of Sarmiento's intelligence and imagination. *Travels* compiles long letters to friends in Argentina and Chile, to whom Sarmiento wrote about the places he visited, the personalities he encountered, political institutions, the customs of dress and entertainment; or in short, the wide array of circumstances and events that he came across during his long journey that began in Valparaíso and ended in the United States (Sarmiento, 1993).

The epistolary form and the topical material that is characteristic of travel literature allow Sarmiento to jump from one topic to another, from a descriptive story to portraits of individuals that left impressions on his spirit as he roamed the world. He wanted to see and feel those cities that he had heard about but only knew through reading – from Montevideo to Rio de Janeiro in South America, to Paris, Madrid, Rome, Munich, Berlin, and Oran (an African colony), then to New York, Baltimore, Philadelphia, and Washington. Of course, Sarmiento was obsessed with the fate of the South American people, who he deemed backward, and thus wanted to write about useful things, about lessons that could help his people. He did not neglect, on the other hand, the fulfillment of the mission that motivated the trip: the study of public education in the countries he would visit, work that he would also consider in *Popular Education*. But at the same time, he did not hesitate to stick his nose everywhere he wanted. The Paris that he discovered was much like the Paris of his readings, i.e., the cultural center of the civilized world. But upon a closer look, French society appeared much more unequal than he had imagined. The months he was in Spain only confirmed what he already knew: the country was stuck in an earlier time – the spirit of the Inquisition and Phillip II still reigned. Spain was a country that did not know itself – he observed that every new idea entered Spain just as it would enter South America: as a rendition, a copy, not as the original thing. Sarmiento dedicated many pages to the bullfights, an entertainment that he judged as cruel and barbaric but strangely seductive. The ancient metropolis, the seat of the former Spanish Empire, in short, could not be the example of progress for its former colonies.

What dazzled Sarmiento the most about his travels was the sociopolitical experiment that was taking place in North America, as he confessed in a letter about the United States. Not everything about the US seemed admirable to Sarmiento, but he admired everything he judged as essential to the social experiment and the behaviors upon which it rested: industriousness, simplicity, and the intelligence to appropriate, generalize, and perfect all the methods and instruments of progress, all of which were shown to be within the reach of man. He paid close attention to the most varied aspects of his experience, and especially to those aspects for which he had no prior model: immigration from Europe, the electoral system, even the homogeneous style of the houses. What he saw in the US, as he mentions to a friend, was not the republic he had dreamed of, but rather, without doubt, what accompanies democracy.

Some argue that from a purely literary viewpoint, Sarmiento's the best book is his autobiography, *Memories of Provincial Life*, published in 1850, when he envisioned that the Rosas dictatorship was coming to an end. Rivals dismissed the book as a self-serving self-portrait of an aspiring presidential candidate. There is, of course, some truth in this depiction, but it would be wrong to reduce the text to a simple political ploy. *Memories* was not the first time Sarmiento wrote in defense of his merits and honor; nor was it a secret that he had a high opinion of himself. *Memories of Provincial Life* also reads as a defense of Sarmiento's public career. Nevertheless, a good part of the book is a reminiscence of ancestors and life in the province before and after independence. What mattered to Sarmiento, in other words, was not only the history of himself, but the local portion of a larger past from whence he came. In this evocative text, the discussions of customs take turns with physical and moral portraits, political and historical judgments, family memories and the vicissitudes of one's biographical path. In short, *Memories of Provincial Life* weaves autobiography with history as he praises his Creole lineage and subsequent career. Sarmiento understood, first and foremost, that he was the progeny of his works (Altamirano and Sarlo, 1997).

Sarmiento and His Interpretation of South American *Caudillismo*

The *caudillo* and *caudillismo*, the century-long domination of continental politics by military leaders after liberation, have been important issues in the historiography, social thinking, and the Hispanic narrative throughout South America. The book that began this tradition is Sarmiento's *Facundo*, making this a celebrated work of intellectual history, not only for Argentina, but also for all of Spanish America (Sarmiento, 2012). This famous work originally appeared as a series of installments in the Chilean newspaper *El Progreso* that he directed. Announcing the publication of this work, Sarmiento alleged that what had driven him to write the series was the desire to counter the Rosas propaganda against Argentinian emigrants in Chile. But even in the introduction, he realizes that his ambition was more than simply adding another chapter to the abundant anti-Rosas literature. His ambition was to explain the Argentinian civil wars and the nature of *caudillismo* in South America; to tell a biographical tale, full of strange and interesting events, within an environment that was still uncultivated; to disseminate an outline of a political and social agenda.

Why a biography? Sarmiento loved the genre, which can be attributed to his enormous cognitive and pedagogic power. He thought the synoptic capacity of the biography (the life of an eminent individual, a representative man) would allow for an evocation of the customs and spirit of an age and simultaneously make historic events accessible to the people. *Facundo* is thus not a work of historical scholarship, but it is a work of historical and sociological imagination (Salomón, 1984). Sarmiento had cultivated this imagination in his diverse readings – the historical novels of Walter Scott; then later, with the literature of the Romantic movement in France. Later, in Chile, there would be the discovery of a new history, a new way to conceive and practice the study of the past, that of historic Romanticism. The authors he praised were Francois Guizot, Augustin Thierry, and Jules Michelet. As Sarmiento saw it, France was the center of a historic vision that fascinated him,

namely, the view that philosophical history, inherited from the Enlightenment, could be expanded into a social history that included in its scope not only the customs, belief, and institutions of civil and governmental life, but also the action and confrontation of collective social and cultural forces (Orgaz, 1940).

The eminent individual, the representative man, of the book is the Argentinian *caudillo* Facundo Quiroga, a real person and not a fictional creation. In Sarmiento's eyes, Facundo was not just a *caudillo*, but the incarnation of a social force, an organic expression of Argentinian life as it had been created by Spanish colonization and the peculiarities of the physical space, of the vast plains of the Pampa. The task of the book is to explain this character and his social projection by the data of the physical and historical environment in which he lived. Hence the two parts that divide the history of Facundo: the first, which fills the first four chapters, involves the landscape of the nearly uninhabited Pampa, the stage on which he is going to represent the historical drama; then secondly, which covers the final nine chapters, the exegesis of the protagonist with his fierce appearance, his ideas and his way of working. The author believed that in this he was adopting the principles of the Romantic conception of history, where a harmony exists between the character and his environment, that each mutually reflects the other (Halperin Donghi, 1996).

The stage in which the figure of the *caudillo* will make its appearance, in his most authentic emanation, is the Pampa. In this vast and sparsely populated plain, long populated by Indians and Spaniards and their joint offspring the *mestizos*, Sarmiento observed that the colonial years entailed a way of life already forged that was distinct from that in the urban centers. Primitive, hard, and exposed to the immediate pressures of the environment, and distant from the law and doctrines of the city, the way of life of the countryside cattle rancher had created its own customs and social types, among which the exceptional character was the *gaucho*, the Pampa's cowboy. The knowledge and skills required to survive in this environment were rigorous – skill with the horse and the knife, the skills of the *baqueano* (trail guide), and the *rastreador* (tracker); and also the values of the habitants of this elemental world. The essential requirements for the rudimentary tasks of the cattle rancher and *gaucho*, their lives permanently surrounded by danger, are the stuff of epics. Life was rough, unsocialized; reputation meant nothing. What produced fame were the abilities of the gauchos and their performance in constant tests of physical courage. This was the environment of 'barbarism,' a term that in the ideological language of the day was a diatribe. And the antithesis of this barbaric space is the city. The city is the realm of law, commerce and ideas, the nucleus of 'civilization,' or at least a European-style civilization but surrounded by South American nature, the Pampa, the desert. The city is the place for cultivated, scholarly men.

Sarmiento observed that until 1810 – when the revolution began – two forms of human establishment, two societies, one next to the other, coexisted in the future territory of Argentina. Both resulted from the combined forces of South American nature and Spanish colonization and each unfolded in its own context. Each of these two societies sheltered its own spirit and principles. One was the city, the seed of European civilization or civilization itself; the other was the countryside, the cradle of barbarism, the antagonist of civilization. Both remained indifferent to each other until the revolution of 1810 put them into active contact.

The revolution, Sarmiento observed, was in fact two revolutions that largely ignored one another until external forces drove them into conflict. One was the revolution against Spanish domination, and it was driven by European ideas of freedom, progress, and modern institutions and largely led by the intellectual elite. The other was the revolution against the city, led by the gauchos, cattle ranchers, and military men who embraced 'barbarism.' Sarmiento formulated an interpretation of the era that, to him, shed light on the Argentinian convulsions. The revolutionary movement, in short, activated a double struggle: the war in the cities that fought against the Spanish by those seeking advancement of a more refined European culture; and the war against the cities, fought by the *caudillos*, representing the spirit of the countryside. The object of this second war led by the *caudillos* was not to put an end to Spanish authority, but to all authority and civil order. For the countryside, the revolution was only an opportunity to deploy, in a larger arena, all the tendencies that were hostile to the civilized spirit of the city.

Within this interpretive formula, which Sarmiento thought would clarify the issues that were tearing apart Argentinian political life, the story of the life of Facundo Quiroga begins. If this interpretative scheme explained the conditions and general trends that set the stage for the emerging *caudillo* in the province of La Rioja, the biography proposed a further link to a singular and representative destination, namely the discontinuous and scattered elements of collective history. In the exposition, Sarmiento develops a 'language of knowledge' – an historical science of the 'new way of being,' the American spirit, which in his view had not yet received adequate intellectual representation.

Sarmiento was not unaware of the 'poetic side' of barbaric life and at times his text delivers an admiring description of the nature and personalities of the crude and elemental rural world. However, Sarmiento (like Romantic Argentinians in general) accompanied his teachers, the European Romantics, only to a certain point: he did not look for nor did he discover the pastoral Eden, the culture of the original people, a culture that had been lost in the cities through the works of a cosmopolitan civilization. The aesthetic value of the countryside, the admiration of the wisdom of the cattle rancher, the empirical wisdom of the *baqueano*, or the inspiration of the singing gaucho do not imply a critique of progress nor a corrective to civilization. The reality of the barbarians, in Sarmiento's mind, was foreign and exotic, not the wellspring of an autonomous or alternative society.

What Sarmiento valued in the idea of civilization was not only civilized habits and institutions – manners, refinement of customs, the schools, the courts, business, the arts of industry, the cultivation of readings, etc. – but also something even more basic, something that can be captured in what the countryside shepherd does not provide. And that is the regular contexts that promote interactions among men, interactions that can moderate the impulses of 'natural' (unsocialized) men and generate a sense of and interest in the public good. The city, in contrast, multiplies the sites for these interactions. While the pastoral countryside disperses its habitants and their energies,

the city concentrates them and inserts them in the settings of civilization. Finally, the city engenders public space – space for animated deliberation, space where enlightened citizens can express themselves. Thus, the countryside destroys itself when its representatives seize the city. From that moment forward, opinion can no longer limit power. For Sarmiento the *caudillo* regime is a kind of despotism, a type of government in which one commands without submitting to any law.

Sarmiento did not invent every element of this interpretation of the social world that existed before the movement that began in 1810. But his book was never intended or described as the fruit of a learned and serene study. Rather, it is a book of combat and confrontation. There is a fierceness of the pamphlet that often seizes Sarmiento's text. This fierceness tirelessly curses the *caudillos* but then prophecies a bright future when the country would open itself to European immigration and allow for the navigation of its interior rivers.

Posterity has judged that this magnificent book was not just wrapped in the political passions of that time. Sarmiento and his *Facundo* do not live just in the libraries, scholarly studies, and university teaching: they also live in the ideological debates that occurred in Argentina in the twentieth century, especially after 1930, and that continue to the present day. Indeed, the *Facundo* still inspires concern about the two Argentinas, about the antagonism between scholars and *caudillos* that some believe summarizes Argentine national history. Still, neither the figure of Sarmiento, the intellectual legislator, nor that of *Facundo*, the barbaric *caudillo*, resonate solely within Argentinian culture. They resonate throughout contemporary Latin America (Brading, 1992).

Satisfaction and Commitment in Long-Term Heterosexual Relationships

Aaron Ben-Ze'ev, University of Haifa, Haifa, Israel

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Satisfaction and commitment are crucial for maintaining long-term heterosexual romantic relationships. In light of the relatively brief duration of emotional experiences and the abundance of alluring romantic alternatives, maintaining a long-term romantic relationship is seen to be 'against all odds.' The presence of many tempting alternatives to the present relationship generates romantic compromises and makes it extremely difficult to be happy with one's own relationship. In order to ensure their long-term survival, there is a need to revise the nature of heterosexual relationships. A nurturing approach is suggested for this purpose.

Profound Satisfaction and Superficial Pleasure

Satisfaction involves pleasurable feelings as well as an element of fulfillment associated with contentment. When you are satisfied, you feel good about what you have and what you have achieved; you have had enough and you are happy with it.

Profound activities have a lingering impact upon our life and are essential for our development and flourishing. Superficial activities have a more limited impact: they affect only the surface of our lives; their impact becomes significant only if we frequently engage in them. Profound satisfaction, which is associated, for example, with profound love, profound involvement in work, or profound intellectual activities, is essential to human flourishing since it involves optimal functioning that, over time, develops the agent's essential capacities and attitudes. Part of profound satisfaction is the ability to overcome problems and feeling a sense of self-fulfillment while doing so. Superficial pleasure, such as that derived from, for instance, casual sex, watching television or gossiping, is an immediately rewarding, relatively short-lived experience requiring few or no profound human capacities.

Fulfilling ideal romantic love which endures for a long time is hard to achieve and hence low satisfaction and feeling of being romantically compromised are quite common. Unlike the total and uncompromising nature of ideal love, in reality, love comes in degrees and entails various types of behaviors. Preventing dissatisfaction typically requires idealization and positive illusions. While extreme romantic beliefs generally tend to engender unrealistic standards, a certain degree of idealization is usually beneficial.

Life is complex, and we cannot have it all. Knowing our limitations is one of our great virtues. Perhaps one secret of profound satisfaction in heterosexual relationship is not striving for the best of all worlds where passionate romantic love is always in the air in an intense manner, but rather knowing how to be satisfied with one's smaller lot, which might not always be filled with such love. Love is important, but love is not all you need.

Being satisfied with your own lot does not necessarily mean lowering your standards, but rather the ability to see the positive aspects of your situation. Ideals are necessary in human life, but it is useful to be aware of the limitations that reality poses upon the fulfillment of our ideals. Accordingly, compromises are inevitable. Any substantial disregard of reality is likely to lead to other problems.

Commitment in Long-Term Heterosexual Relationships

Commitment involves a pledge to do something in the future. Robert Sternberg (1988) suggested that romantic relationships characteristically have three major components: intimacy, passion, and commitment. Intimacy expresses closeness, bonding, and connection. Passion is largely the expression of desires and needs and is expressed in physical and mental arousal. Commitment is the extent to which a person is likely to stick with someone and see her or him through to the end.

Commitment is essential for long-term romantic relationships; thus, the lack of it has been found to be a significant predictor of relationships breaking up. Commitment theory distinguishes between factors that motivate connection versus factors that increase the costs of leaving. Loving someone motivates us to establish a romantic connection with that person, while being married discourages us to leave the relationship because of its high cost. Commitment theory adds another important factor: the alternatives to the present situation. Commitment can be seen then as the degree to which attracting forces overwhelm repelling forces, despite the given alternatives. Commitment is strengthened by the amount of satisfaction and the extent of the cost, and weakened by possible alternatives to that relationship. Satisfaction level was found to be significantly more predictive of commitment than were the quality of alternatives or the amount of cost of separation. This suggests that the quality of the relationship has the greatest impact upon its continuation, much more than external factors such as the cost of switching or the available alternatives. However, when satisfaction is not high, the extent of the cost and the attractiveness of the alternatives can be quite significant (Benjamin and Agnew, 2003; Jones and Adams, 1999; Rusbult, 1983).

At the basis of the psychological objections to marital commitment is the fact that while marriage is a committed, stable mode of living, intense emotions are essentially transient and unstable states. Taking love to be the essence of marriage runs the risk of ruining either marriage or love. In response to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.35035-8

this objection, it can be claimed that a commitment to love is not aimed at creating emotions from scratch; it is aimed at sustaining an already-present dynamic. A commitment to love does not imply manipulation of emotions; it implies the intention to ignore the inevitable periods in a relationship when the emotion of love is not experienced. Marriage is an act of placing trust in the relationship, rather than merely hoping or expecting it to succeed. Such a trust is essential, since it tends to be self-fulfilling. Indeed, many contemporary marriages still last for life. Nevertheless, commitment to a relationship remains conditional on the partnership retaining its value.

Difficulties in Maintaining a Long-Term Romantic Relationship

Two major factors increase the difficulties of maintaining satisfaction and commitment in long-term heterosexual romantic relationships in present-day society: (1) the great role that changes play in generating emotions, and (2) the greater plausibility of leaving a current relationship and starting a new one. These two factors significantly reduce commitment to and satisfaction from current relationships.

The first difficulty, which is related to the nature of the emotional system, refers to the fact that intense emotions are typically transient and unstable states, whereas stability is needed to generate the satisfaction we experience in long-term committed relationships. Emotions are usually experienced when we perceive a significant change in our situation (Ben-Ze'ev, 2000). Whereas change intensifies emotions, commitment entails stability. Although long-term relationships involve some changes even as they remain intact, the most significant change, that is, changing the partner, is absent. The sexual excitement and satisfaction experienced initially with a new partner is often difficult to sustain in long-term relationships, as routineness takes over. However, the importance of sexual excitement remains high, and marital satisfaction is associated with sexual desire (Brezsnyak and Whisman, 2004).

The second major difficulty for maintaining satisfaction in long-term romantic relationships refers to certain developments in current society that have increased the availability of romantic partners. In current society, we are witnessing the lifting of most of the constraints that once prevented long-term committed relationships from dissolving; another factor in this regard is the apparent presence of many attractive alternatives.

Nowadays, being satisfied and staying within a committed relationship has become a more difficult option – one that requires the partners to constantly reexamine the value of their relationship in light of, among other issues, the presence of love. Lovers might face not only constant doubts about which road to take, but also constant regrets about the many roads not taken. The abundance of alternatives and the perpetual possibility of achieving something 'better' can undermine commitment and satisfaction.

The notion of the availability of alternatives may explain many seemingly puzzling situations, such as people who remain in unsatisfied marriages or jobs. Although their satisfaction from the present situation is low, these people perceive other possible alternatives to be even worse. The other direction is found as well: people leave reasonably satisfied situations for unknown risky ones; this is because the evaluation of possible alternatives often supersedes those of existing positions. Since the realm of infinite romantic possibilities so overwhelms us with tempting alternatives, we are unable to reasonably consider the present situation as romantically satisfactory. We have become slaves of the possible and spoilers of the present.

Having the freedom to choose between many alternatives has its own cost; excessive freedom can increase people's uncertainty, insecurity, dissatisfaction, and depression. Therefore, the availability of a greater choice can be a mixed blessing. Indeed, sometimes adding options makes the task of choosing less attractive and more cumbersome; consequently, there are people who (occasionally) prefer others to make choices for them. For example, many people in loveless marriages would be happy if their spouse initiates a separation, rather than having to raise the issue themselves. As Barry Schwartz (2000) shows, too much freedom from constraints is a bad thing, as unconstrained freedom leads to paralysis and becomes a kind of self-defeating tyranny. He argues that due to the multiplicity of choices available at all times and on all fronts, people no longer know how to be satisfied with 'just good enough.' They always seek perfection. Such freedom also undermines the notion of deep commitment and social belonging to groups and institutions, bonds that are vital to our mental health. Freedom constrained by ideals and boundaries may in fact be more satisfying and less dangerous than unconstrained freedom.

The above difficulties make romantic dissatisfaction a real threat to marriages and other committed relationships. The feeling of being romantically compromised becomes more dominant.

Satisfaction and Romantic Compromises

The need to make a commitment indicates that there is a potential conflict between long-term satisfaction and the commitment. However, both commitments and satisfaction are important parts of human social life.

In romantic compromises, we give up a romantic value, such as romantic freedom and intense passionate love, in exchange for a nonromantic value, like the wish to live comfortably without financial concerns. Nevertheless, in our hearts we keep yearning for the road not taken – the one with greater romantic freedom and with a more attractive partner (Ben-Ze'ev, 2011).

We may discern two major types of romantic compromises: (1) compromises on romantic freedom that are made when entering a marriage (or another committed relationship), and (2) compromises on the choice of partner. Romantic compromises involve two major concerns: (1) giving up alluring possible alternatives while still yearning for them, and (2) accepting negative aspects of the partner. Both concerns are present in the two types of compromises, but with different weightages. The concern regarding giving up alluring alternatives is high at both types of compromises but higher in the first. The concern regarding accepting negativity is mainly present in the second type.

In the type of compromises referring to the choice of the partner we may discern two major subtypes: (1) compromise on the overall value of the person, and (2) compromise on the value of the person as a romantic partner. In the first subtype, we compromise on something very essential to intimate relationships: having a partner who is up to our standards. Although this is strictly speaking not a romantic compromise, it typically leads to such a compromise as we feel that we deserve more. The second subtype expresses the very core of romantic compromise – there is no profound romantic love in this relationship – as something essential for love is missing. Whereas giving up romantic freedom underlies the inherent romantic compromise in marriage, the dissonance between the ideal, perfect partner and the actual partner is at the center of the compromise in choosing the partner. Due to the perceived nature of the ideal beloved, it is almost impossible to find such a person. However, when we take into account our own flaws, nonperfect people may be seen as perfect enough.

Both types of romantic compromise – giving up romantic freedom and accepting a partner with obvious flaws – indicate the necessity of compromise in committed romantic relationships. Many couples in less-than-perfect marriages would stay together if they understood that compromise is an essential feature of married life as well as of any other committed relationship. These people take an unnecessarily harsh view of their marriage because they fail to perceive the value of compromise in a less-than-perfect world. On the other hand, many people stay in a rotten relationship because they do not understand the difference between 'good' compromise and 'bad' compromise.

Factors Influencing Satisfaction and Commitment

So far, I have discussed some general considerations concerning satisfaction and commitment. There are other types of factors influencing satisfaction and commitment, for example, age, gender, education, religion, socioeconomic level, and personal characteristics and attitudes. I will now discuss a few of those factors that are most relevant to the above considerations. I focus on inequality, respect, sacrifice, age, and personal space.

Inequality

Two major types of inequality in heterosexual relationships are (1) inequality in a comparative status and (2) inequality in emotional involvement. These types of inequality correspond to the two subtypes of romantic compromises: (1) compromising on the overall value of the person and (2) compromising on the value of the person as a romantic partner.

Concerning the first kind of inequality, the equity theory postulates that those involved in an inequitable romantic relationship consider themselves to be undeserving of the situation and hence their satisfaction and commitment are considerably reduced. This is the case both for those perceived to be inferior, who feel guilty for receiving more from the relationship than they feel their partner does, as well as for those perceived to be superior, who feel that they deserve more. Involvement in extramarital relationships, which expresses both low commitment and low satisfaction, may serve as a way of compensating for such inequity. The 'superior' people may perceive extramarital relationships as something they deserve because their spouse gets more from the marriage than they do. The 'inferior' people tend to be involved in extramarital relationships in order to escape the unpleasant state of inequity and to prove to themselves and to their partner that they actually are deserving and attractive to the opposite sex (Prins et al., 1993). Indeed, feeling inferior to one's partner is associated with less commitment, less satisfaction, and less love for the partner (Murray et al., 2005).

In a similar vein, people who stand to lose the most are apt to be the least likely to risk ending the relationship by having another sexual partner. People who feel that they are compromising will be more likely to take romantic risks. Thus, if the woman has a higher level of education than her partner, she is more likely to risk the relationship by having a secondary sexual partner than if both members of the couple have equal levels of education (Forste and Tanfer, 1996).

In the short term, the inequities might give rise to great admiration and hence may increase love and sexual desire. Thus, people who can provide us with social status, such as the rich, the famous, and the powerful, will generate more intense sexual desire and sexual satisfaction. In these cases, we are less likely to feel that we are compromising. A similar impact can be found in the other direction; a low level of an admirable characteristic, such as intellect, reduces sexual satisfaction. In the long term, significant inequalities become problematic for both sides, whereupon superficial short-term goals (such as being associating with a famous person) become less important. For example, the 'higher status' person may begin to show a lack of reciprocity, which will eventually damage the 'lower status' person's love and could even generate negative emotions such as envy, jealousy, and anger.

The situation is made more complex by the fact that the extent of the gap and the overall comparative value of each partner also play a part. Inequality in certain domain, such as attractiveness, can persist if the overall comparative value is similar. In these circumstances, the partner's inferiority in one domain may be compensated by superiority in another. Thus, when people are certain of their worth, they may prefer a partner who is a bit superior to them in one domain and hence will be more beneficial for them. In this case, admiration may be the relevant emotion. Thus, in one study, 89% of high-achieving men report that they would like to marry or have already married a woman who is as intelligent as they are, or who is more so (Whelan, 2006). These men believe that in marrying such woman they have made the better deal.

We may also speak about unequal emotional involvement between partners. This inequality occurs in most romantic relationships and has a considerably negative impact upon marital satisfaction and commitment, therefore increasing the likelihood of a breakup. The consequences of this inequality have been described as an example of the 'principle of least interest.' The least interested partner is less committed and has more control over the continuation of the relationship. Accordingly, this partner is often (but not always) the one who terminates the relationship (Sprecher et al., 2006). A relationship involving unequal romantic involvement is a compromise for both partners, as the low level of satisfaction is common to both of them; it is less clear who is making the more profound compromise.

Respect

Mutual respect, which is central to marital satisfaction and commitment, is related to the issue of equality. Respect is less likely to present in relationships characterized by inequality in terms of the overall value given to the partnership or inequality in the partners' emotional involvement.

Respect, which is an attitude and not an emotion, is directed toward a partner who is trustworthy, considerate, and accepting. Respect has been found to be a stronger predictor of relationship satisfaction than measures of attachment, love, and liking (Frei and Shaver, 2002). Respect, which involves both caring and equality, enables the partner to enjoy reciprocity, autonomy, flourishing, and personal growth.

A certain measure of distance exists in respect that allows partners to live as they wish, regardless of how good they are to their partner. This respect gives them a personal space, which has its own intrinsic merits. Sexual desire is not about respect, but about breaking distance and boundaries. Romantic love includes both an appropriate distance that allows respect and a close emotional involvement, which is involved in intimate sexual relationship.

John Gottman (1998), who is known for his work on marital stability and relationship analysis, noted that most couples want two main things from their marriage – love and respect. Indeed contempt, which is the opposite of respect, is one of the major predicators of divorce. Another study listed respect as one of four core relationship values, the other three being commitment, intimacy, and forgiveness. Yet another study found that people often mention respect spontaneously when talking about why their relationships function well or poorly and that respect is one of the five most frequently mentioned and valued features in the romantic partner – the others are being accepting, trustworthy, honest, and loyal. Respect was also found to be closely connected with marital satisfaction. Disrespect is a powerful expression of lovelessness in marriages. Respect implies our right to be treated in a way that enhances our positive self-esteem. In intimate relationships, respect implies and asserts equality. The importance of equality in successful marriages and intimate relationships is seen in the crucial role of respect in romantic relationships and the potential damage that lack of respect inflicts on such relationships (Hendrick and Hendrick, 2006).

Sacrifices

In close relationships, the willingness to sacrifice is associated with strong commitment to and high satisfaction in the relationship. Sacrifice is a potent longitudinal feature of marital adjustment. Accordingly, sacrifice is also associated with good relationship functioning and higher quality relationships. People identify sacrifice with caring, trust, respect, and loyalty and hence with what they consider as love. The tendency to sacrifice expresses more profound love and enhances a sense of security, which is assumed to be essential for marital success. The benefits of sacrifice are especially pronounced when people sacrifice in order to promote the other's well-being or to enhance intimacy in their relationship (Impett and Gordon, 2008; Van Lange et al., 1997).

Sacrifices can be harmful when they are extensive and are not reciprocal, such as when one partner (usually the woman) carries the full burden of sacrifice in the relationship. Extensive sacrifices underlie the traditional other-validated model of love in which the other is the ultimate preoccupation of a person's meaningful world. According to this view, sacrificing one's life for the beloved is a reasonable option. It is often the case that people who lack power in their relationships (once again, often women) are more likely to engage in sacrifice. This is made even worse when those making the sacrifice are 'silencing' their own opinions and desires in the relationships.

Reciprocity is important in generating the will to sacrifice, as it indicates that the other is equal to you and will make sacrifices for you if needed. Willingness to sacrifice is associated with greater relationship satisfaction and stability. Despite the fact that sacrifices are intended to promote the others' well-being and not that of the sacrificers, the latter may also benefit from the sacrifice, as it can increase their self-image, enhance others' evaluation of them, and raise the chances that their partner will make sacrifices for them in return. Accordingly, they too might gain from their sacrifice (Impett and Gordon, 2008).

Age

The common assumption that happiness declines with age is mistaken. On the contrary, research indicates that older people are actually happier and more satisfied with their lives than younger people are. One possible explanation is that when we realize that our years are numbered, we change our perspective and tend to focus on meaningful and positive present experiences. Our emotional experiences are more likely to consist of peacefulness and serenity rather than excitement and joy. Sonja Lyubomirsky summarizes these findings by noting that for most people, the best years are in the second half of life (Carstensen, 2009; Lyubomirsky, 2013).

In accordance with the above claims, it was found that older individuals perceive their spouse as warm during both disagreement and collaborative tasks and report high marital satisfaction. Older married couples have fewer marital conflicts than their younger counterparts although they report that erotic bonds are less central in their lives. Companionate love, which is based upon friendship, appears to be the cardinal feature of their lives. Intimate relationships in old age are, by and large, harmonious and satisfying (Berscheid, 2010; Charles and Carstensen, 2009).

Despite the above findings, there are still disagreements concerning the precise nature of the relation between marital satisfaction and age, one reason being that the notion of 'satisfaction' is perceived differently at various ages.

Many studies claim that overall marital satisfaction follows a U-shaped association between marital duration and marital happiness, with satisfaction high in the early years of marriage, relatively low in the middle years, and returning to higher levels in old age (Charles and Carstensen, 2009). This claim is disputable and some studies suggest that the U-shaped results are artifact from the selection process of the married couples. Their studies suggest that marital satisfaction does not increase in the later years of marriage (VanLaningham et al., 2001).

It appears that the ambiguous findings concerning the association between age and marital satisfaction (and with happiness in general) are due to the shifting meaning of happiness and satisfaction at different ages. The main difference is that the meaning of happiness moves gradually from excitement to peacefulness (or contentment) as one gets older (Mogilner et al., 2011).

I will discuss the implications of this claim further in the concluding section. In any case, it seems that the problem of romantic compromises becomes less acute as people grow older. The major factors of such compromises, that is, the presence of negative features in the partner and yearning for the possible, are of lesser weight in old age. Over time, people get accustomed to their spouse's negative aspects. They learn to live with them while minimizing their negative impact. In older age, when people realize that their time is running out and that their available alternatives are decreasing, they are more likely to accept their limitations and not feel they are compromising when they do not pursue an attractive option. Elderly couples more readily take the attitude of being happy with their lot.

Personal Space

The issue of personal space is directly connected to the essence of romantic compromises: giving up a seemingly better alternative and hence yearning for the possible. In a flourishing relationship, the importance of a significant personal space cannot be exaggerated; its absence expresses a profound romantic compromise. Personal space does not necessarily involve sexual freedom. Thus, in commuter marriages, where personal space is significantly higher than in typical marriages, commitment is high and the percentage of extramarital affairs is similar to that of standard marriages; sexual satisfaction is also similar (Gerstel and Gross, 1984; Kelmer et al., 2013; Stafford, 2005).

Online relationships are similar to commuter marriages in having a significant personal space, and in assuming that coresidence is not necessary for loving relationships. However, unlike commuter marriages, commitment in online relationship is very low.

It seems that some kind of distance, providing a greater personal space, is important for close relationships. Distance may focus the partners' attention on the profound aspects of their relationships and help them to disregard the superficial ones. Significant and temporally extended physical distance may harm relationship, but a more limited distance may be beneficial. As the saying goes, "Absence makes the heart grow fonder."

Hedonic Adaptation

Emotions typically occur when we perceive positive or negative significant changes in our personal situation, or in the situation of those related to us. A major positive or negative change significantly improves or interrupts a stable situation relevant to our concerns. Like burglar alarms going off when an intruder appears, emotions signal that something needs attention. When no attention is needed, the signaling system can be switched off. We respond to the unusual by paying attention to it.

In light of the crucial role of change in our emotional life, humans have a built-in tendency to return to a relatively stable level of happiness after major positive or negative events. This phenomenon, which is called 'hedonic adaptation,' suggests that the joys of new loves and new triumphs and the sorrows for new losses will fade with time. Hedonic adaptation constitutes an obstacle for maintaining a high level of excitement and satisfaction in long-term loving relationships. Such adaptation also indicates that long-term profound love is not mainly based on features such as sexual desire, which greatly depend on change and hence are more under the influence of hedonic adaptation; rather, it depends on features such as friendship, caring, and reciprocity, whose value remains constant (and even increases) as time goes by.

Another implication of hedonic adaptation is that romantic compromises are part and parcel of long-term committed relationships. This is so since romantic compromises involve the limitation of one's romantic freedom and the need to be satisfied with a familiar partner, who is less exciting than a new one. However, hedonic adaptation can help us accommodate to a situation that at first is seen as compromise. Moreover, intervention in order to increase one's happiness in marriage is possible if the agent knows about, endorses, and is committed to the intervention (Lyubomirsky, 2013).

Hedonic adaptation works within certain limits. Extreme experiences, such as intense love or intense domestic violence, are typically outside these limits. In some cases, intense love can endure for many years without returning to the basic level of happiness that prevailed before this love. And some people adapt to domestic violence, although it is highly risky for them. As in many other aspects discussed here, hedonic adaptation applies to most average circumstances, but not to extreme situations.

Maintaining Long-Term Satisfaction

Satisfaction in marriage depends upon the couple's ability to be satisfied with their romantic lot. When people are satisfied with their lot, they do not feel that they are compromising. In this concluding section, I sum up a few major related factors that enable couples to maintain long-term satisfaction in marriage: personal flourishing, being integrated in a larger positive framework, and adapting to new criteria of satisfaction.

In seeking to cope with marital dissatisfaction and romantic compromises, the agent's own flourishing and development are of considerable importance. Satisfaction in marriage is not merely about making the beloved happy, but also about working to ensure that the lover is profoundly satisfied with the way in which the relationship is nurturing her own development and flourishing (Ben-Ze'ev and Goussinsky, 2008). The emphasis is shifting here from a model based upon other-validation to one of self-validation (Mitchell, 2002). Only a deeply satisfied person can provide love and happiness to another. The self-validated model is by no means a matter of egocentrism. It is not egocentric to attempt to nurture your capacities and genuine needs, while at the same time developing a loving equal relationship with another person.

The emphasis upon self-worth is also expressed in the central role played by promoting, rather than preventing, types of behavior. Accordingly, caring is more significant in love than prohibiting various types of sexual practices. Likewise, focusing on the partner's uniqueness is of greater importance than focusing on the exclusivity of the lover-beloved relationship.

In profound loving relationships, the flourishing and autonomy of the agent is central; this leaves more options open and reduces the feeling of captivity. The agent's general flourishing, which is expressed in having more options open to her, does not negatively affect her partner. On the contrary, the impact upon the partner is usually positive as well; the flourishing of one partner is likely to improve the relationship as a whole and benefit the other partner as well. This is true in those areas of the agent's life that do not involve the romantic relationship itself; however, in the romantic area itself, too much romantic freedom and the availability of more romantic options often reduce the satisfaction from and commitment to the partner.

The importance of the agent's personal flourishing is related to the importance of establishing marital satisfaction within the larger context of a happy life. In the same way, living healthily is not just eating healthily. It is a complex, dynamic framework that is related to many factors in our physical and psychological environment that determine healthy living; for instance, whether we engage in outdoor activities, are stressed, are socially active, and have balanced meals. The notion of a healthy life is complex and refers to various means taken in different ways and to different extents. Like healthy life in general, a healthy romantic relationship is also a complex framework involving various factors, such as friendship, sexual desire, caring, and reciprocity. The larger framework makes the relationship more solid, as it is based not on one narrow leg but upon a broader foundation.

An important feature in maintaining long-term marital satisfaction is the typical shift that occurs over time in the way that we rate such satisfaction. Cassie Mogilner et al. (2011) claim that whereas in their youth, people are more likely to associate happiness with excitement, as they get older they become more likely to associate happiness with peacefulness. This change involves a redirection of attention from the future to the present as people age. When people's attention is focused on the present, they are more likely to be happy with their own lot.

To sum up, maintaining satisfaction in a long-term marriage (and in other committed relationships) depends significantly on the framework in which this relationship exists. In some aspects, this larger framework extends the satisfaction to other aspects in the people's lives, such as personal flourishing, independent of the quality of the relationship. When people are highly satisfied with their personal activities, it is more likely that they will be satisfied with their relationship with the partner. From another aspect, the focus of the framework becomes more limited with time; in older age, the focus is more on the given present rather than on the larger unknown future. Both such extensions and limitations of the context in which the committed relationship exists can increase people's ability to be satisfied with their lot.

Abstract

Although formally a geographer writing on early humans and agriculture in Mexico and the southwestern USA, Carl Sauer's writings and concerns straddled a wide range of topics, including plant domestication, colonial destructive impacts, modern mass production society, academic freedom, the role of the social sciences, cultural diversity, and environmental quality. His early rebellion against environmental determinism in geography led to collaboration with anthropology and the adoption of culture as the ultimate shaping force in geography. His pithy style and simple, straightforward language meant that latterly he had a following among avant-garde garde poets, literati, and environmentalists in California and elsewhere.

Carl Sauer was one of the towering intellectual figures of the twentieth century, not only in geography but also in a wider intellectual sphere. However, because of his wide-ranging thought, speculative sweep, and world perspective over a number of subjects, it is difficult to define his contribution to the social and behavioral sciences precisely and easily. But one can say that some of his underlying concerns were about scholarship, independence of thought, opposition to academic bureaucracy, a sympathy and identification with rural folk, concern for cultural diversity and environmental quality, and a distaste for the technological and scientific 'fix,' particularly the solutions offered by the emerging social sciences after 1945.

He was born in Warrenton, Missouri on 24 December 1889 of German parents, and because of his background and 3 years of schooling in Calw (near Stuttgart) he was influenced by German culture and literature. He completed his graduate studies at Chicago University in 1915 under the geographer Ellen Semple Churchill, the geologist Rollin D. Salisbury, and plant ecologist Henry C. Cowles, the latter two of whom made a lasting intellectual impression on him. He then taught at the University of Michigan until 1923, when he moved to geography at Berkeley where he taught for 34 years (32 as Chair) and established one of the most distinctive graduate schools of American Geography that would always be associated with 'cultural geography.' After he retired in 1955 he enjoyed 20 remarkably productive years that saw the publication of four books and a score of influential papers, all distinguished by big and speculative ideas, that were the fruits of a lifetime's reflection and unhurried reading. His reputation soared so that an 'aura of sage, philosopher-king, and even oracle surrounded him' (Hooson, 1981, p. 166). He died in Berkeley on 18 July 1975.

Cultural Geography

Sauer rebelled against the sterile environmental determinism of contemporary geography with its emphasis on humans as response mechanisms to physical factors. If nothing else, his experience in the Economic Land Survey in the Michigan Cutovers had shown him that humans radically transformed the earth, often for the worse, and in the process created cultural landscapes. In his search for a new, humane geography, cultural anthropology seemed to offer a means of dealing with the diversity of humankind and its cultural landscapes through time. On arriving in Berkeley he found natural soul mates in the anthropologists Alfred L. Kroeber and Robert H. Lowie. The concept of 'culture' subsequently pervaded all his teaching and writing. In *The Morphology of Landscape* he distilled an almost wholly German geographical literature, established the primacy of human agency in the formation of cultural landscapes 'fashioned out of the natural landscape by a cultural group,' and the importance of a time-based approach. In addition, he placed great importance on observation and contemplation in the field – a *Verstehen* or empathetic understanding and intuitive insight into behavior or object in order to achieve 'a quality of reasoning at a higher plane' than the tangible facts (see Sauer, 1925; Williams, 1983).

Sauer wrote 'Morphology' in order to 'emancipate' himself from determinist thinking and, with a few more papers on the cultural landscape of the midwest frontier, he put the epistemological game behind him and started substantive field work on early settlement and society in Lower California, Arizona, and Mexico. During the 1930s he produced many works, including *Aztatlan* and *The Road to Cibola* both published in a new monograph series *Ibero-Americana* that he founded in the same year with Alfred Kroeber and the historian H. E. Bolton. (For these and many other of Sauer's publications see Leighly, 1963.) These investigations drew him into the controversy about New World plant domestication and plant origins, and into collaboration with botanists, archeologists and ethnologists, whom he found congenial intellectual company.

Widening Horizons

All the time Sauer's horizons were getting wider, his ideas more speculative, and his ethical values more refined. Toward the end of the 1930s he wrote a slight, but ultimately influential, paper which was a sustained and biting critique of the destructive social and environmental impact that resulted from the predatory outreach of Europe, which had few counterparts at that time except, perhaps, in the writing of Karl Marx (Sauer, 1938). He drew inspiration from the work of George Perkins Marsh on the human transformation of the earth and

Ernst Friedrich's concept of *Raub-wirtschaft*, or destructive exploitation (see Marsh, 1865, 1965; Friedrich, 1904). His experience and knowledge of Latin and Central America and their history suggested to him that the Spanish conquest had led to a devastating and permanent impoverishment of the land and of its cultures and societies. Disease, warfare, and enslavement had disrupted traditional value systems. Thus, the diffusion of technologically superior societies could affect humans and their culture just as much as it could physical resources.

But two works more than any others established his world reputation and heralded a remarkable decade of multifaceted yet interrelated speculative understanding of the place of humans on earth. First was *Agricultural Origins and Dispersals* (Sauer, 1952a) that flowered later into a string of publications into the human uses of the organic world, and early humans in the Americas from the Ice Age onward. Unfortunately, radiocarbon dating came too late to inform Sauer's writing, but although he may not have provided the answers, he defined the questions brilliantly.

Second, in 1956, with the collaboration of Marston Bates and Lewis Mumford, he masterminded the Princetown symposium on 'Man's Role in Changing the Face of the Earth,' the theme of which thereafter became his overriding interest. (See Mumford, Lewis (1895–1990).) All his learning and concerns culminated in this volume, and in his chapter "The Agency of Man on Earth" (Sauer, 1956). The capacity of humans to alter the natural environment – the 'deformation of the pristine' – the cult of progress and waste that stemmed from mass production ('commodity fetishism'), and the alien intrusion of humans into world ecology, were included. In contemporary terms, the theme was the degradation of the environment, and it was an early and influential statement. It also had another dimension: globally, the 'imperialism of production' was as bad as the old, colonial imperialism, and might ultimately be no better than Marxist totalitarianism; mass culture was eliminating not only biological diversity but also cultural diversity, and older and less robust societies. Somehow, humans had to rise above this mindless, short-term exploitative mode. 'The high moments of history have come not when man was concerned with the comforts and displays of the flesh but when his spirit was moved to grow in grace.' Therefore, what was needed was "an ethic and aesthetic under which man, practising the qualities of prudence and moderation, may indeed pass on to posterity a good Earth" (Sauer, 1956, p. 68).

His simply articulated ideas had a resonance with many activists and intellectuals, as well as Californian avant-garde poets and literati, who extolled his work as an example of cultural and ecological sensitivity and respect, tinged with deep historical insight and scholarship, and made attractive by his simple and pithy language. He also tapped a deep spring of feeling during the 1960s and 1970s at the time of Vietnam and student unrest with their concerns at the limits of the earth and technological/political power. Yet Sauer was a complex mix. He was congenitally nonconformist but deeply conservative, and although profoundly concerned with conservation was never formally an 'environmentalist,' and indeed, he thought the movement was little more than an 'ecological binge.'

Distrust of the Social Sciences

In many ways it is ironical that Sauer has a place in this *Encyclopedia* because he had such a deep distrust and distaste for the behavioral and social sciences. Although he eschewed methodological and epistemological discussion, his writing, and particularly his personal correspondence, reveal that he was "a philosopher in spite of himself" (Entrikin, 1984). Culture history became his model of social science, and it was drawn from the natural sciences, not the social sciences. He was basically a pragmatist who was influenced by the writings of the German cultural geographers Friedrich Ratzel and Eduard Hahn, and by the methods of geology and anthropology and their emphasis on the provisional character of working hypotheses which were no more than a means to an end. His later association in Berkeley with people who worked on 'tangible things,' like plant ecologists, agricultural scientists, botanists (e.g., Ernest Babcock), experts in the evolution of population genetics (see Wright, Sewall (1889–1988)), and geneticists reinforced this.

He argued for a theoretical and methodological pluralism that stemmed naturally from the inherent diversity of nature and culture. The natural science idea of a dynamic balance and diversity that arose from organic evolution was embedded deeply in his thought, and he felt that the modern world had disrupted these processes so that it was out of balance. Hence his deep distrust of US capitalism and all bureaucratic systems which would destroy diversity and local community. Liberal social scientists who designed, planned, and directed community life were more likely to destroy than enhance it by imposing universalizing concepts of social organization, and by ignoring the inherent pluralism and diversity of nature and culture that stimulated the naive curiosity about the world which was the essence of geography. Theoretical and normative social science as practiced by economists, sociologists, and political scientists, grated on him with its exaggerated confidence in the statistical and the inductive, and its 'dialectic atmosphere.' Their focus on the present precluded a better insight into the origins and evolution of any topic, and gave 'an exaggerated accent on contemporaneity.' His social science was based firmly in history and geography – this was culture history.

During the late 1930s he talked jokingly of the two patron saints of social scientists – St. Bureaucraticus, who represented rationalism and professionalism in US academic life, and St. Scholasticus, who represented social theorists who sought normative generalizations about humankind and society. Consistently, these 'Sons of Daedalus' were the target of his criticism because their well-funded procedures and programs emasculated the independence of the impressionable younger scholars (Williams, 1983).

His address, 'Folkways of the Social Sciences' was an eloquent, if not audacious, plea to social scientists to 'give back the search for truth and beauty to the individual scholar to grow in grace as best he can' and to reinstate time and place into the study of the USA (Sauer, 1952b).

Sauer's other *bête noire* – mass production – promoted the homogenization of society, not only in the USA but globally, as the USA firmly assumed the position of superpower during the 1950s, with what he saw as a disdain for the 'lesser breeds.'

Sauer was aware that he was 'out of step' with his colleagues and intellectuals, and spoke of himself as an 'unofficial outsider' and even as a 'peasant.' This has been typified as part of the antimodernism that characterized early twentieth century US intellectual life. But it went much deeper than that; his ideas anticipated society's fears and disenchantment with progress, science, the elimination of diversity, and the degradation of the environment. Perhaps the ultimate relevance of Sauer's work was in his groping toward a *rapprochement* between the social sciences, the humanities, and the biological life sciences. By being behind he was far ahead.

Abstract

Few scholars have left on their discipline the mark Ferdinand de Saussure left on linguistics. After his death, the publication of the Course in General Linguistics was perceived as a turning point in the discipline and a move toward a more systemic, structural analysis of language. Saussure's ideas – as conveyed in the Course – greatly influenced the rise of French Structuralism and, consequently, cultural studies in the whole realm of the humanities and the social sciences.

Saussure's Interdisciplinary Legacy

Ferdinand de Saussure is known today as one of the founding fathers of modern semiotics, as a forerunner of structuralism, and as a thinker who has influenced several generations of scholars not only in linguistics, but in all the disciplines that were touched by the 'cultural turn' that started in the 1960s and 1970s. Ironically enough, this huge intellectual status is posthumous and apocryphal. Saussure's fame derives mainly – one might say almost exclusively – from a work, the *Cours de Linguistique Générale* (Saussure, 1916), which was edited from the notes of the three courses he taught in the period 1907–11. The *Cours* was published in 1916, three years after Saussure's death, and in a few years' time it gained the reputation of being a turning point in modern linguistics. From then on, it acquired a life of its own and became a 'totemic' text.

During his lifetime, Saussure was seen under a quite different light: a precocious enfant prodige, able to write a landmark work in Indo-European linguistics (Saussure, 1879) at age 21; a man whose perfectionism prevented him from being a prolific author; a scholar who sometimes struggled to follow his great intuitions with systematic presentations of his findings; a prominent expert in historical and comparative linguistics.

There are therefore many Saussures, depending on the angle from which we consider his figure. For the majority of his readers, Saussure is today the 'author' of the *Cours*, and especially the author of the part of the *Cours* that deals with the general principles of linguistics. But time has led also to a philological reconstruction of his ideas, and to the discovery of surprisingly modern positions on semantics and pragmatics that could not always be reconciled with the legacy of his masterwork.

Education and Career

Saussure was born in Geneva on 26 November 1857 from a distinguished Protestant family. From a very young age, he developed an interest for poetry and the study of language, following the tracks of his maternal grandfather Alexandre-Joseph, himself an amateur linguist. The family was more known for its contribution to the natural sciences, starting with Saussure's great-grandfather Horace-Bénédict (1740–99) and his great-uncle Nicholas-Théodore (1767–1845). His father Henri, on his part, was an amateur entomologist and an agronomist. Following the steps of these renowned relatives, Saussure enrolled at the University of Geneva in 1875 with the prospect of becoming a scientist himself. There, he took courses in chemistry and physics, but also in philosophy, history of art, and classical languages. Perhaps the burden was too heavy, since Saussure missed his chemistry examination and, the following year, his father agreed to his transfer to Leipzig, where he would study linguistics full time.

Leipzig was at the time a very important center for linguistics, where the legacy of Romantic philology was being challenged by the group of scholars that were half-mockingly described as the *Junggrammatiker* (the Neogrammarians). In Leipzig, Saussure was able to form a network – not always characterized by easy relationships – with some of the most prominent scholars of his time. Saussure studied with Georg Curtius (1820–85), the doyen of linguistics at Leipzig, and with younger scholars including Hermann Osthoff (1847–1909), August Leskien (1840–1916), and Karl Bruggman (1849–1919) and others, well-versed in many of the languages of the Indo-European family.

By that time, Saussure had also established fruitful contacts with the other important center of linguistics in Europe, Paris. It was a move that would have important consequences on his career. In 1876, Saussure applied for membership in the Societé Linguistique de Paris, and accompanied the application with a paper on the suffix *-t-* that was quickly accepted for publication (Saussure, 1877). For years to come, Saussure played a central role in the activities of the Societé, on whose board he served for many years as Adjunct secretary. The *Mémoires de la Société de Linguistique de Paris* became the journal where the majority of the articles he published during his lifetime appeared. Thanks to his affiliation to the Société, Saussure became acquainted with the work of French linguists, like Michel Bréal (1832–1915), Gaston Paris (1839–1903), Louis Havet (1849–1925), Arséne Darmesteter (1848–88), as well as Antoine Meillet (1866–1936), his most gifted student and later a prominent linguist and a member of Émile Durkheim's interdisciplinary circle.

Despite the early acceptance of his work by Parisian linguists, Saussure was still a student in Leipzig. After the series of short papers that appeared on the *Mémoire* in 1877, Saussure began work on a much more ambitious project, one that in his

vision would advance comparative linguistics to a higher level, in terms of methodological approach and conceptual rigor. For the better part of 1878, Saussure rushed to finish a manuscript that became a breakthrough work in Indo-European linguistics. The *Mémoire sur le systéme primitif des voyelles dans les langues Indo-Européennes* (Saussure, 1879) was a 300-page book and the work for which Saussure gained acclaim and recognition during his lifetime.

In this book, which he self-published, Saussure hypothesized the existence of a sound in Proto-Indo-European (which he identified as A, although he was careful to claim that it had an unknown phonetic value). Saussure's A, in combination with other 'sonant coefficients,' would develop into various phonemes. With this ingenious internal reconstruction and with a move toward abstraction, Saussure was able to build a rigorous hypothesis on the dynamics of *ablaut* (i.e., vowel variations) in the Indo-European linguistic system, an hypothesis that was going to be proved only in 1927 by Polish linguist Jerzy Kuryowicz. More than the technicalities of Saussure's ingenious solution, or the advancement in the knowledge of Indo-European phonology, the *Mémoire* is most notable today for it contains the kernel of some assumptions that Saussure would develop in his unpublished work on linguistics and that would eventually lead to the lectures of the *Cours*. Saussure was among the first to use a modern concept of 'phoneme,' and his view of language as a system that works through the combination of interrelated parts that acquire meaning only as part of that system finds is advanced for the first time in the *Mémoire*.

Soon after, Saussure defended – *summa cum laude* – his doctoral thesis on the genitive absolute in Sanskrit, an ambitious work on the origins of the form, which he was not able to complete to his full satisfaction and which was published as *De l'emploi* (On the Use) *du génitif absolu en sanscrit* (Saussure, 1881). He then spent a period at his family home in Geneva and made an unproductive field trip to Lithuania (the interest for Lithuanian returned in later years on his work on accentuation). In September 1880, he moved to Paris, where he spent the next decade in the nontenured position of maitre des conferences at the Ecole des Hautes Etudes.

While in Paris, Saussure carried on his duties as a preeminent member of the Societé Linguistique. He also began to write in a more systematic matter on topics related to general linguistics, although it was with frustration that he realized that he was not able to bring any of these projects to its completion. Indeed, many of the themes that appear in the *Cours* were already being sketched by the beginning of the 1880s in unfinished manuscripts like his notebooks on phonology of 1881 (where he discussed the linearity of language and used the term 'semiotic'), the relationship between sound and idea, and the necessity to complement historical analysis with the study of language as a 'state' when dealing with 'semiological facts' (Joseph, 2010; Joseph, 2012: 306; Saussure, 2006).

Saussure was unable to secure a chair in Paris, where politics played a major role and his Swiss nationality acted as an obstacle in the context of the Third Republic. That was probably the reason why he moved back to Geneva in 1891, where he was appointed as extraordinary professor of Sanskrit and Comparative Grammar, a position that was made permanent with the institution of a chair of Comparative Philology in 1896.

The first years in Geneva were, as it had happened in Paris, years of methodological and theoretical reflection that form the bulk of the unpublished manuscript concerning the 'double essence' of language (Saussure, 2006: 3–60) in which he pointed out the difference between vocal sounds and meaningful signs. Only when ideas are attached to vocal sounds can language exists. Nor this was the only idea that anticipated the contents of the *Cours*. The notes contained in "On the Double Essence" also deal with issues of synchrony and diachrony, and with the proposal of Saussure's theory of *value*, which is determined by contrast, opposition, and difference with other signs.

It would take more than a decade before Saussure started the cycle of lectures that made him posthumously famous and in which these ideas were made public. Following the retirement of one of his colleagues, he was assigned the task of teaching a course in General Linguistics that took place every other year. Saussure taught three courses: in 1907, 1908–09, and 1910–11. The students' notes from these courses, and some of Saussure's own notes, constitute the bulk of what became the *Cours*. It was the second landmark work in his intellectual trajectory, although he did not live enough to see this success. Saussure died on 22 February 1913.

The Course in General Linguistics

The decision to publish a book out of Saussure's notes was made soon after his death. It was a daunting task because he had not planned to write a book on general linguistics and he had left very few systematic notes. What became the *Cours* was thus put together using some of Saussure's manuscripts, and mostly students' notes from the three courses.

The *Cours* was published in 1916, after three years of gestation and editing by two of Saussure's colleagues, Charles Bally and Albert Sechehaye, with the contribution of Albert Riedlinger (a student who had attended the first course in 1917). Bally and Sechehaye, who were among the first bearers of Saussure's flag, have sometimes been accused of assembling a text that reflected more their own visions than Saussure's focus on historical and comparative linguistics.

Today, the picture is much more accurate. Not only Saussure's writings on general linguistics have been found and published, but the material on which the *Cours* as published was drawn has been made available, including critical editions of the *Cours*, annotated editions, and the students' notebooks for all the three courses.

While these sources offer us a clearer idea of how the three courses were organized, and follow the development of Saussure's arguments, for the broader audience it was the *Cours* as originally published that had considerable influence, especially the long introduction and the section on the general principles for the study of language. In these sections, that represent the starting point for any foray in the work of Saussure, a powerful framework is proposed, with concepts that have shaped not only contemporary linguistics but many other disciplines: the distinction between *langue* and *parole*, and between synchronic and diachronic; the analysis of the linguistic sign and its

arbitrariness; the theory of linguistic value; and the analysis of the types of relations among signs, at the syntagmatic and the associative level. These are the main tenets of the *Cours*, and have represented for many a milestone in the development of structuralism and semiology, the general science that Saussure promised and of which his linguistics was a particular application.

The Main Tenets of the Course

The *Cours de linguistique générale* is an exploration that seeks to find the object of linguistics, its relation to other facts connected to language (mainly, its concrete use by speakers), the nature of linguistic units, and how they contribute to the stability or change of the linguistic system. The *Cours* is not – in Saussure's vision and in the one of his editors' – a speculative work on language. It is, on the contrary, the ambitious attempt to construct linguistics as a scientific and rigorous enterprise by defining its object and its position *vis-à-vis* other social sciences.

Saussure's argument for the definition of the object of linguistics proceeds by subtraction and abstraction. His key idea is that language needs to be studied as a system (he rarely used the word 'structure,' and never in the technical sense that was popularized decades later), which is composed by interrelated linguistic units whose function can be described only with reference to other elements of the system. Only in this way the systematic character of language can emerge, against the background of the heterogeneous mass of linguistic phenomena.

The strategy of isolating the system in analytic terms leads Saussure to the formulation of the first major dichotomy that is present in the *Cours*: that between the use of language in acts of speaking (*la parole*) and language as a socially shared repository of signs and rules (*la langue*). This distinction separates what is individual in the execution of language from what is social, the latter being the proper object of linguistic analysis. While the *parole* requires an individual *act* in a communicative situation, the role of the individual with regards to the *langue* is less as an agent and more as a repository of representations that are fundamentally transindividual.

This distinction is clear in Saussure's description of the speaking circuit, which involves a 'psychological phenomenon' (the association of a sound-image to a concept), a 'physiological process' (the emission of sound), and a 'physical process' (the transfer of sound waves through the air to the ear of the listener). The analysis of the *langue* is interested only in the first of these aspects, while the others belong to the *parole*. Linguistics – and semiology as a broader, more encompassing science of signs as part of social life – is therefore a part of social psychology, whose object is the nature of the association – a largely mental phenomenon, however socially shaped – between sound-images (signifiers) and concepts or ideas (signifieds).

This is Saussure's second major dichotomy. The vision that a sign entails the relation between an expression and a conceptual counterpart is not a radical invention on Saussure's part, and has many antecedents in the history of philosophy of language. Quite radical, with the hindsight of a hundred years of reception of the *Cours*, is the combination of antireferentialism and arbitrariness that Saussure sees as key elements of linguistic signs.

Saussure's antireferentialism is one important consequence of his distinction between langue and parole. Language (as *la langue*) is not a naming process that relates words to things in the world. Rather, the linguistic sign is the association of a 'sound-image' and a 'concept,' not the one between a word and a thing. Like words and things, however, signifiers and signifieds are in a special relation with peculiar characteristics. They are both required to signify and they cannot be separated from the concrete point of view, as 'each recalls the other' like the two sides of a sheet of paper that cannot – fronte and verso – be cut. The linguistic sign is therefore an intimate unity between two sides that could not be conceivable without each other.

The relation between the signifier and the signified is a particular one, characterized – according to Saussure – by two fundamental principles: the arbitrariness of the sign and the linearity of the signifier. Arbitrariness is one of the fundamental concepts of Saussure's *Cours*. Given the internal solution that he favors in the definition of the object of linguistics, the arbitrary nature of the sign does not mean the arbitrariness of its relationship with an external object. It is an *internal* arbitrariness that takes place between the signifier and the signified. By this, Saussure means that there is no motivated relation within the sign, that is., there is nothing natural in the association of a given signifier to a given signified; it is, by all measures, the result of social activity that gets crystallized in a particular form, the sign.

The concept of linearity is often overlooked, but it is important in order to understand the types of relations that exist *among* signs, and not only *within* signs. Being of auditory nature, a signifier can be conceived only as it unfolds in time: its representation is a line. This formal constraint governs the way signifiers are organized: at least in language, two different signifiers cannot occupy the same position at the same time. They can appear either as distinct elements in a succession, or one can substitute the other, creating thus a different value or meaning.

To understand this fundamental proposition, one need not to consider signs in isolation, but the types of association that exist among signs. Saussure – in his usual dichotomic fashion – argues that relations among signs can be either syntagmatic or associative (later, Jakobson would use the term 'paradigmatic'). These relations work in different ways: while syntagmatic relations are characterized by the succession of syntagms in a linguistic chain (and thus are characterized by presence or copresence of signs in a syntagmatic chain), associative relations are part of a 'mnemonic series' that brings together signs that have something in common (they work in absentia).

The three dichotomies that Saussure had proposed in the *Cours* are of fundamental importance to describe the internal mechanisms of the langue and the types of relations that exist within the langue. The historical dimension does not play an important role, even though there is an internal dimension of temporality that is crucial to understand how the langue works. The last dichotomy addressed the issue of linguistic change and historical comparison. A langue, in principle, can and must be approached in a static way, by producing a description of the configuration of the system at a particular moment where

structural changes do not occur. This is what Saussure means by synchronic analysis. A diachronic analysis, on the contrary, considers at least two different states of language that are not only temporally distinct, but in which the use of language has produced socially accepted changes that have invariably altered the system.

Langue/parole, signifier/signified, synchrony/diachrony, and syntagmatic/associative are the four major oppositions that Saussure proposes in his strategy to build linguistics on scientific grounds. In the reception of Saussure's work, the synchronic approach to the langue has taken a central position outside the boundaries of linguistics. While this runs contrary to many of Saussure's interests and to the core of intellectual orientation (he was, and always had been, mainly a comparativist) it was through the adaptation, rereading and to some extent even misunderstanding of the *Cours* that he was able to secure a central position as a revolutionary thinker for generations of scholars.

Saussure after the *Cours*: Reception and Adaptation

Saussure's legacy as one of the most prominent linguists of his generation was secured, ironically, by words he had not written and by positions that were made probably more radical than he had originally thought. Like many classic works (Max Weber's *Economy and Society*, Antonio Gramsci's *Prison Notebooks*, or Ludwig Wittgenstein's *Philosophical Investigations*), it mattered less what he had actually said, and more the use one could make of his words. The decades that passed after the publication of the *Cours* have thus been characterized by the attempt to reconcile different – sometimes radically different – visions of Saussure: the comparativist, the founding father of structuralism, the institutionalist, the scholar who promised – but did not realize – the foundation of a new science like semiology (Harris, 2003; Sanders, 2004).

To all the parties involved in this retrospective reconstruction, the *Cours* is still the door to Saussure's vision of linguistics. One could work, however, with the *Cours* or despite the shadow it casts on his 'author.' This tension often meant the effort to go beyond the published work and reconstruct a more authentic Saussure with the aid of his original writings.

The reception of the *Cours* came in waves. Even in its 1916 incarnation and other editions (1922, 1931) the *Cours* took some time before it was perceived as a foundational work in linguistics, and again it happened thanks to the mediation of scholars who stretched some of the main positions it contained in order to fit their own goals. Early reviews were mixed, and the reception of the *Cours* took place in a milieu still characterized by different research paradigms (historical linguistics in France and descriptivism in the United States) that were at odds with Saussure's emphasis on synchronic analysis, although the *Cours* found some champions in both countries, like Meillet and Leonard Bloomfield (1887–1949). On their part, Soviet linguistics criticized the *Cours* for its lack of attention to extralinguistic forces, despite Saussure's own caveats and his insistence on the existence of an 'external linguistics' (a sociological critique advanced by philosopher Valentin Voloshinov, 1929).

The trajectory of the *Cours*' appreciation turned for the better at the end of the 1920s, when linguistic structuralism was about to become a recognized tendency. Louis Hjelmslev (1899–1965) in Copenhagen and Nikolai Trubetzkoy (1890–1938) and Roman Jakobson (1896–1982) in Prague acted as the main agents in this new appreciation of the *Cours*, one that – despite criticism and substantial changes – stayed true to the book's perceived program of static, synchronic, and formal linguistics. However, they also called for a renewed attention to problems that Saussure had dismissed or neglected, like the relation between form and substance, the type of function established between a signifier and a signified, the importance of the phonological level, and issues of semantics and pragmatics that are not present in the *Cours* (although some of these problems are hinted at in the *Writings on General Linguistics*).

Hjelmslev's and Jakobson's work (Hjelmslev, 1928, 1953; Jakobson, 1995) was at the same time more formal than Saussure's and more explicit in the definition of the conceptual boundaries of semiotics as a discipline. Saussure had defined linguistics as a discipline that could analyze the role of signs in the context of social life, but had devoted just a few suggestive pages to the role of semiology and its position *vis-à-vis* the other psychological and sociological disciplines. To him, general linguistics was part of semiology insofar as it could describe the systemic character of *la langue* and its units (signs). But, when it came to semiology, he characterized it as a science that did not yet exist.

Hjelmslev started mainly from these premises, but criticized three crucial aspects of Saussure's approach to the l*angue*: his cognitivism (the langue is embedded in the human mind), his attention to the orality of language, and the lack of analysis of the semantic level. From Saussure, Hjelmslev derived a hierarchical vision and an inclination for dichotomic classification, in some cases specifying Saussure's ideas, and in others creating a new conceptual toolbox that complemented Saussure's: form and substance, expression and content in lieu of signifier and signified, system and process as internal patterns of relations.

Jakobson's work proved even more influential in the popularization of Saussure, even though he always remained very critical with regards to the rigor of the categories that Saussure had adopted. Starting from work on phonology in the 1920s, Jakobson became the true herald of structuralism in linguistics. However, he also developed a line of inquiry that was broader than Saussure, even when he seemed to change little from Saussure's ideas: Jakobson's notions of code and message are note a mere translation of Saussure's *langue* and *parole*, but the attempt to integrate linguistics with information theory; his idea of syntagmatic and paradigmatic relations is more formal than Saussure's, without the focus on the open-endedness of chains of signs that assigned to associative relations; his model of communication describes functions that apply to any kind of manifestation of language, including poetic texts.

While Saussure was commonly perceived as the originator of structuralism, it was however through the work of these scholars that structuralism became a true intellectual force starting from the 1940s (Dosse, 1998a,b). Saussure's ideas were incorporated in this attempt to shape structuralism (and, within structuralism, semiotics) as a theory and a method. From this point of view, this meant a reversal of the *Cours*' insistence on linguistics as a province of semiology. Rather,

linguistics became the paradigm for the development of semiotics, insofar as all semiotic phenomena were organized as a language or could be analyzed as a language (Barthes, 1968).

The rise, and the almost sudden wane, of structuralism meant another turn in Saussure's reception. The *Cours*' editors had imagined and portrayed Saussure as a generalist interested in synchronic analysis. Barthes and those associated with structuralism (among the most prominent ones, one could mention Maurice Merleau-Ponty, Jacques Lacan, Roman Jakobson, Claude Levi-Strauss, and Algirdas Greimas) offered another mediation, that focused on linguistics as a discipline that could offer a paradigm, as well as a vocabulary modeled after Saussure but highly different from Saussure's intent and scope: a toolbox made of binary oppositions, codes and messages, deep structures, generative models, that could be stretched in the effort to be connected to Saussure's ideas, but which represented also a creative (and fruitful) betrayal of Saussure as much as they were a betrayal of the *Cours*.

Meanwhile, Saussure's figure and work were being subject to a more careful scrutiny in order to come to a genealogical reconstruction of his ideas (Godel, 1957; Koerner, 1973). Saussurean studies were less interested in extending the application of Saussure's ideas than they were in trying to figure out how the *Cours* represented the synthesis of reflections that Saussure had made during his entire life.

This genealogical work took several directions, and the rediscovery of Saussure as a general linguist was not without surprises. It was possible to trace Saussure's interest for theoretical issues back to his Paris years. The appearance – and then publication – of Saussure's *Writings in General Linguistics* (2006) allowed for more careful consideration of the path that had led him to formulate his vision of the linguistic sign, the role of semiology and the tasks of the discipline. While new scholarship on Saussure did not radically change the picture, some of the assumptions that scholars had made about the course had to be tuned according to the availability of handwritten notes that included – crucially – his own lecture notes for the *Cours*, which complemented the students' notebooks critically edited by Eisuke Komatsu (Saussure, 1993, 1996, 1997).

Thus, we can argue that today there are many Saussures, depending on the prevalence of either a philological approach or a creative reconstruction of his image. Both camps, however, pay homage to a highly original thinker, regardless of the many mediations that have made his work available. While linguistics, semiotics, and cultural studies have fruitfully moved 'beyond Saussure,' he is still a relevant turning point, the originator of lines of inquiry, even when theoretical reflection goes against his positions. The very fact that we think of all these approaches as developments that took place 'after Saussure' and thanks to this work, is perhaps the best testimony of his intellectual legacy and of the conceptual power of his proposals.

Abstract

L. J. Savage was born in Detroit in 1917 and obtained a mathematics Ph.D at the University of Michigan. After a series of posts, he went, as a statistician, to the University of Chicago in 1946, staying until 1960. He then returned to Michigan, before going in 1964 to Yale, where he died in 1971. He is today principally known for his 1954 book *The Foundations of Statistics*, the first seven chapters of which develop an axiomatic approach to decision-making under uncertainty. The main result is that the uncertainties should be described by probabilities, the worth of the outcomes by utilities, and that the best decision is that obtained by maximizing expected utility. This approach is today usually described as Bayesian. Although Savage developed it as a justification for accepted statistical practice, it effectively destroyed that practice, instead producing a system based on probability as a degree of belief. The remainder of his life was devoted to exploring the consequences of his approach. In this he worked with the great Italian probabilist, de Finetti and, with Hewitt, proved an important extension of a major result of the Italian. He also wrote a book on gambling with Dubins. For social scientists, the main importance of his work lies in the construction of a belief system about the world as appreciated by a single individual.

L. J. Savage, always addressed by friends as Jimmie, was born in Detroit, Michigan on 20 November 1917. His father was in the real-estate business, his mother a nurse. Throughout his life he suffered from poor eyesight, a combination of nystagmus and extreme myopia, which was to affect the development of his career in many ways. Most of us accept reading as an easy, even casual, activity, whereas to him it was a serious business with the text held close to the eye. The result was that he appeared to regard the material as important and would absorb it with an intensity that often escapes those with normal vision. To have him read something you had written was, at first, an uncomfortable business, for he would politely question much of the material, but later to realize that he was being constructive and the final result benefited enormously from his study of it. He was a superb lecturer, once remarking that he could hold himself spell-bound for an hour. When, towards the end of his life, he gave the Fisher lecture, he held the audience spell-bound for considerably more than the allotted hour.

The poor eyesight at first affected him adversely, his high-school teacher not recommending him for further education. His parents were insistent and he went initially to Wayne University and then to the University of Michigan. His attempts to do biology failed because he could not draw, and chemistry was ruled out when he dropped the beaker in the laboratory. Eventually he met a fine mathematics teacher who introduced him to a field in which the reading had to be intense, yet minimal, where his brilliance was recognized and he gained a Ph.D in the application of vectorial methods to metric geometry. After a year each at Princeton, Cornell, and Brown, 1944 found him a member of the Statistical Research Group at Columbia University, a group he described as 'one of the greatest hotbeds statistics has ever had,' a judgement that is surely sound, as almost all those who were to become the leading statisticians in the US of the 1950s were in the group or associated with it.

So he became a statistician, and although his greatest work was in the theory, as such he was able to indulge his interest in science, so that throughout his career he enjoyed, and was extremely good at, consulting with his scientific colleagues. It was not just science that interested him, for he had inherited from his father a respect for business, and had acquired from Milton Friedman, a member of the group, an appreciation of economics, that made his advice useful and generously available to all serious thinkers.

In 1946, Savage went to the University of Chicago where, from 1949, he was in the Statistics department founded by Allen Wallis, becoming chairman from 1957 until he left the university in 1960. His departure was a turning point in his life. A reason for leaving was personal difficulties in his marriage to Jane Kretschmer that they hoped could be mended by a move to Michigan with their two sons, Sam and Frank. It did not work out and they were divorced in 1964. That year he married Jean Pearce and moved to Yale. It was in New Haven on 1 November 1971 that he tragically died at the early age of 53, and statistics lost a great scholar and many of us a dear friend. The move from Chicago was partly influenced by his perception of his relations with colleagues there. He felt, as we will see below, that he had produced a sound axiomatization of statistics showing that many standard statistical procedures were unsatisfactory, so that his colleagues should either explain where the axioms were wrong, or else abandon the faulty procedures. They did neither. They were not alone in this; most statisticians acted as the Chicago faculty, refusing to contest the axioms, yet refusing to use the results (many still do so today) and Savage found it difficult to get a suitable post until Yale obliged. The monograph by Savage with others (1962), although now rather dated, indicates the sort of antagonism that existed, though, in that book, all the protagonists are on their best behavior. Savage (1981) contains most of his more important papers, tributes from others and a technical summary of his work. Many of his papers, contained therein, deal, not with technicalities, but with his growing appreciation of statistical ideas as they developed throughout his life.

Savage is justifiably famous for one tremendous contribution to statistics and the scientific method, contained in his 1954 book *The Foundations of Statistics*. Or, to be more correct,

[†] Deceased.

the first seven chapters of that book. Anyone contemplating study of this glorious achievement should first read his preface to the second edition in 1972, for this is one of the most honest pieces of scientific writing that I know. To appreciate the importance of the book, it is necessary to cast one's mind back to the state of statistics around 1950. Fisher made enormous advances from 1920 onwards. Neyman and Pearson had introduced new ideas and Wald was developing decision analysis. But the statistical procedures available, though undoubtedly valuable and much appreciated by scientists, especially biologists, were a disparate collection of ideas lacking coherence. Savage had the idea that statistics should be like other branches of mathematics and be based on a set of concepts, termed axioms, from which the procedures would follow as theorems. He wanted to provide a firm basis for Fisher's results. Another way of understanding is to recognize that Fisher had suggested procedures whose properties had been studied by him and others, whereas Savage turned the method around and asked what properties we wanted and discovered what procedures provided them. His expectation was that they would prove to be just what statisticians were using. To his great surprise, they were not. Interestingly, his last paper, Savage et al. (1976), is a brilliant, sympathetic review of Fisher's work.

Savage had worked with von Neumann in Princeton and had much appreciated his work on games with Morgenstern (1944), that introduced axioms leading to the concept of a utility function for the outcomes of a game. However, their treatment had used probability without justification, so Savage conceived the idea of developing an axiomatic system for decision-making under uncertainty which would not use probability in the axioms but derive it in theorems, so uniting the ideas of probability and utility. Also influential was the development by Wald (1950) of an attempt to unite statistical ideas under the concept of decision-making, using von Neumann's idea of minimax, but lacking any axiomatic foundation. Savage's 1954 book presents axioms for a single decision-maker, now often referred to as 'you,' faced with selecting a course of action in the face of uncertainty. He then proves three theorems: first, that your various uncertainties present must combine according to the rules of probability; second, that your perceptions of the merits of the possible outcomes that result from your actions must be described by a real-valued utility function (which is itself based on probability); third, that your optimum decision is that which maximizes your expected utility (MEU), the expectation being evaluated according to the probabilities developed in the first part of this trilogy. One of the axioms he used encapsulated a simple notion that has since been seen to be of some importance. If you prefer A to B when C is true and, at the same time, prefer A to B when C is false; then you prefer A to B when you do not know whether or not C is true. It is called the 'sure-thing' principle because the preference of A over B is sure, in American parlance, at least as far as C is concerned.

The introduction of MEU was not new, it having been used by Daniel Bernoulli in the eighteenth century, but the development extended its use considerably, in particular by showing that it was the only sensible method for a single decision-maker to use. Utility had recently been explained, as we have seen, by von Neumann. The original and dramatically important result was the first, saying that probability was the only sensible description for uncertainty, so that the rules of probability were not arbitrary but dictated by the sensible and modest requirements expressed in the axioms. Others, from Laplace onwards, had used probability without justification: Savage showed that it was inevitable. So it was the extensive and unique use of probability that was Savage's main contribution in the book, and there are two ways in which his analysis was influential.

First was the fact that the probability was personal, expressing the uncertainty of the decision-maker, 'you.' It was not *the* probability, but rather *your* probability. An immediate reaction is that this contradicts the very nature of the scientific method which is supposed to yield objective results. This apparent contradiction was resolved in a later paper with Edwards and Lindeman (Savage et al. 1963), which showed in the principle of stable estimation, that under general conditions, people with different uncertainties would reach agreement on receipt of enough data. This result agrees with the observation that scientists typically disagree with one another in the early stages of an investigation but are eventually brought together as the evidence accumulates. Many now think that the reduction of uncertainty, through data, incorporated in the laws of probability, expresses the nature of induction and is part of the scientific method.

A second, influential factor was the result that probability was the *only* sensible description of uncertainty, for scientists, encouraged by statisticians, had been using other methods, for example in the use of tail-area significance tests of a null hypothesis, H, where the relevant quantity is the probability in the tail of a distribution, given that H is true. Savage's argument was that the proper evaluation is the probability of H, given the data, not of an aspect of the data, given H. Similar contradictions arise with confidence intervals for a parameter which involve probability statements about the interval, not about the parameter. These are instances where his conclusions clashed with standard practice, leading to disagreements like that at Chicago mentioned above.

There was a third way in which Savage's ideas contradicted the current practice, though this was not fully realized until Birnbaum's (1962) paper. The axiomatic development showed that if you had a statistical model with probability $p(x/\theta)$ for data x given parameter θ, then the only way the data could affect your uncertainty of θ, given x, was through the likelihood function $p(x/\theta)$ expressing how that probability varied with θ for the fixed, observed x. This is the likelihood principle. Significance tests clearly violate the principle since they use a tail-area which involves integration of $p(x/\theta)$ over x-values, that is, over data that you do not have. Indeed, many statistical procedures, even today, violate the principle. A related example of conflict with current practice is found in optional stopping. It had long been known that, under commonly occurring circumstances, it is possible to continue sampling until a null hypothesis is rejected at any preassigned significance level, so that you can opt to stop at your convenience. Savage showed that it was the significance test that was at fault, not the stopping procedure.

It is an astonishing fact, that he explains in the preface to the second edition, that he and others who worked with him, including myself, in the mid-1950s, did not appreciate these ideas and did not comprehend that, rather than his work

justifying statistical practice, it altered it. The latter part of his book in which the justification is attempted, largely using the tool of minimax that von Neumann had employed with great effect in the theory of games, is today of little interest, in contrast to the brilliance of the early chapters. Savage was a true scholar, a man who studied the work of others and accepted any valid criticism of his work, to incorporate their ideas with due acknowledgment. And so he understood the ideas of Ramsey (1926) who had, in a less rigorous presentation, developed similar ideas, ideas which no one had understood until Savage. But more importantly, he appreciated the work of the Italian, de Finetti, who, from an entirely different standpoint, and one which is perhaps more forceful than Savage's, developed the concept and uniqueness of personal probability. (For English readers, the best references are de Finetti (1972, 1974, 1975), though his ideas originate in the 1930s.) Savage acquired skill in Italian and worked with him. One of the problems de Finetti had studied was your assessment of probability. You are uncertain whether it will rain tomorrow in your city; so according to their thesis, you have a probability for rain. How are you to assess its value? De Finetti suggested a scoring rule: if you choose p as your value, you will receive a penalty score $(I - p)^2$ if it rains and p^2 if not. Scores for different events will be added. To minimize your total score the values that you give must be probabilities. The basic paper was written by Savage (1972) with due acknowledgment to the originator. With Hewitt (1955), Savage also extended significantly another result of de Finetti on exchangeability.

Savage conducted a major study with Dubins that resulted in their book (Savage and Dubins, 1965). The problem here is that you are in an unfavorable gaming situation at a casino and your object is to maximize your chance of winning a fixed sum of money; how should you play? They showed that boldness pays; bet all you have or the maximum amount the casino will allow. This led to a thorough study of betting strategies and many interesting and useful results were obtained.

For reasons that are not entirely clear, the school of statistics that rests on Savage's results is called Bayesian, after the eighteenth century cleric, Thomas Bayes partly because much use is made of Bayes's theorem. Today it is a flourishing school of statistics with a large and increasing number of adherents, that co-exists alongside the earlier school, often called frequentist because probability therein refers to frequency, whereas to a Bayesian it expresses your uncertainty of an event. Bayesians believe that their approach to the handling of data, and the making of decisions that use the data, is important for social and behavioral sciences for the following reasons.

If these subjects are to be truly scientific, their arguments must depend heavily on data which, properly interpreted, can be used to defend theories in the interplay of theory and practice that is the scientific method. In the physical sciences, the data ordinarily take the form of results of planned experiments in the field or laboratory, experiments which can, and should be, repeated by others, in accord with stable estimation, their repetition connecting naturally with frequency. In the social sciences, such planning and repetition is rarely possible, so that reliance has to be placed on observational data, and the behavioral sciences are scarcely better off. It is now widely appreciated that observational data have to be analyzed with considerable care, so that any conclusions are soundly based and not confounded with other factors that the lack of planning has been unable to control. Statistics therefore becomes a more important ingredient in the social, than the physical, sciences. Furthermore, social decisions must often be made in the face of uncertainty, whereas more time and effort by an experimental scientist can substantially reduce, if not eliminate, the uncertainty. The Bayesian approach recognizes and incorporates all of these factors.

There is another sense in which the Bayesian approach may be valuable and that lies in its ability to express uncertainty about any aspect of a study, not confining probability to the repetitious, frequency aspects. Often the conclusions in the social and behavioral sciences are tentative and the personalistic perception of probability, as a measure of your belief in a hypothesis, can provide an expression of uncertainty that can be conveyed to others. We still have a long way to go in employing these ideas, when even a weather-forecaster is reluctant to say there is a probability of 0.8 that it will rain tomorrow, or, if he does, sometimes does not appreciate the meaning of what is being said.

Savage had been described as 'the Euclid of statistics' in that he did for statistics what Euclid did for geometry, laying down a set of axioms from which, as theorems, the only sensible statistical procedures emerge. As with Euclid, other geometries will emerge, so other statistical systems may arise, but, for the moment, Savage's Bayesian approach is the only systematic one available and appears to work. He was, in the sense of Kuhn, a true revolutionary, who overturned one paradigm, replacing it by another without, at first, realizing what he had done.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

James D. Wright
Orlando, Florida

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Scale in Geography

Daniel R Montello, University of California, Santa Barbara, Santa Barbara, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Scale is about size, and is one of the most fundamental issues in geography and other disciplines that study phenomena distributed over the earth's surface. The concept of scale has at least three referents: cartographic scale, analysis scale, and phenomenon scale. It is widely recognized that in order to observe and study geographic phenomena most accurately, the scale at which they are mapped and analyzed must match the actual scale of the phenomena. Scale is also important in part because it is closely allied with the problem of the generalization of geographic information.

Scale is about size, either relative or absolute, and involves a fundamental set of issues in geography (Howitt, 2003; Hudson, 1992). Scale primarily concerns spatiality in geography, and this article focuses on spatial scale. However, temporal scale and thematic scale are also important. Temporal scale deals with the size of temporal units; an example is a process that changes on a daily versus annual basis. Thematic scale concerns the grouping of entities or attributes into classes; an example is studying lakes versus water bodies versus landscape features. Whether spatial, temporal, or thematic scale in fact has several meanings.

Three Meanings of Scale

The concept of scale can be confusing, insofar as it has multiple referents (Sheppard and McMaster, 2004). Cartographic scale refers to the depicted size of a feature on a map relative to its actual size in the world. Analysis scale refers to the size of the unit at which some phenomenon is empirically measured and analyzed, such as at the county or state level. Phenomenon scale refers to the size at which human or physical earth structures or processes exist in reality, regardless of how they are studied or represented. Although discussions of scale frequently treat the three referents independently, they are in fact interrelated in important ways that are relevant to all geographers, and the focus of research for some. For example, choices concerning the scale at which a map should be made depend in part on the scale at which measurements of earth features are made and the scale at which a phenomenon of interest actually exists.

Cartographic Scale

Maps are smaller than the part of the earth's surface they depict. Cartographic scale expresses this relationship, traditionally in one of three ways (Muehrcke et al., 2001). A verbal scale statement expresses the amount of distance on the map that represents a particular distance on the earth's surface in words; for example, '1 cm equals 10 km.' The representative fraction (RF) expresses scale as a numerical ratio of map distance to earth distance; for example, 1:500 000. As compared to a verbal scale statement, the RF has the advantage of being a unitless measure. Finally, a graphic scale bar uses a line of particular length drawn on the map and annotated to show how much earth distance it represents. A graphic scale bar has the advantage that it changes size appropriately when the map is enlarged or reduced. Alternatively, all three expressions of scale may refer to areal measurements rather than linear measurements; for example, a 1-cm square may represent 1 ha on the earth. This areal expression is nontraditional.

Given a map image of fixed size, as the size of the earth surface it represents gets larger, the RF gets smaller (i.e., the denominator of the RF becomes a larger number). Hence, a 'large-scale map' shows a relatively small area of the earth, such as a county or city, and a 'small-scale map' shows a relatively large area, such as a continent or a hemisphere of the earth. This cartographic scale terminology is frequently felt to be counterintuitive when applied to analysis or phenomenon scales, where small scale and large scale usually refer to small and large entities, respectively.

An important complexity about cartographic scale is that flat maps invariably distort spatial relations on the earth's surface, due to the intractable problem of displaying a round earth surface on a flat image. Of course, spatial continuity is always violated, as flat images must have discrete edges even though the near-spherical earth surface has no such edges. Distances, directions, and shapes can never be shown accurately everywhere on a map surface, although particular maps can show subsets of such properties accurately. In fact, only the areal sizes of global features can be shown accurately everywhere across the map image, and very often they are not shown this way. How maps distort spatial relations is part of the topic of map projections. In many projections, especially small-scale maps that show large parts of the earth, this distortion is extreme so that linear or areal scale on one part of the map is very different from that on other parts. Variable scale is sometimes shown on a map by the use of a special symbol or multiple symbols at different locations.

Analysis Scale

Analysis scale refers to the size of the units in which phenomena are measured and the size of the units into which measurements are aggregated for data analysis and mapping. It is essentially the scale at which geographic phenomena are

understood. Terms such as 'resolution' or 'granularity' are often used as synonyms for the scale of analysis, particularly when geographers work with digital representations of the earth's surface in a computer by means of a regular grid of small cells in a satellite image (rasters) or on a computer screen (pixels). Analysis scale here refers to the area of earth surface represented by a single cell.

It has long been recognized that in order to observe and study a phenomenon most accurately, the scale of analysis must match the actual scale of the phenomenon. This is true for all three domains of scales – spatial, temporal, and thematic. Identifying the correct scale of phenomena is thus a central problem for geographers. Particularly when talking about thematic scale, using data at one scale to make inferences about phenomena at other scales is known as the cross-level fallacy (the narrower case of using aggregated data to make inferences about disaggregated data is well known as the ecological fallacy).

Geographers often analyze phenomena at what might be called 'available scale,' the units that are present in available data. Many problems of analysis scale arise from this practice, but it is unavoidable given the difficulty and expense involved in collecting many types of data over large parts of the earth's surface. Geographers have little choice in some cases but to analyze phenomena with secondary data, data collected by others not specifically for the purposes of a particular research project. For example, census bureaus in many countries provide a wealth of data on many social, demographic, and economic characteristics of their populace. Frequently, the phenomenon of interest does not operate according to the boundaries of existing administrative or political units in the data, which after all were not created primarily to serve the needs of geographic analysis. The resolution of image scanners on remote-sensing satellites provides another important example. Landsat imagery is derived from thematic mapper sensors, producing earth measurements at a resolution of about 30 by 30 m. However, many phenomena occur at finer resolutions than these data can provide.

It would be very useful to have a theory about the scale of a phenomenon's existence. Frequently lacking this, but realizing that the available scale may not be suitable, geographers use empirical 'trial-and-error' approaches to try to identify the appropriate scale at which a phenomenon should be analyzed. Given spatial units of a particular size, one can readily aggregate or combine them into larger units; it is not possible without additional information or theory to disaggregate them into smaller units. Even given observations measured at very small units, however, there is still the problem of deciding in what way the units should be aggregated. This is known as the modifiable areal unit problem (MAUP, or MTUP in the case of temporal scale), and concerns not only the appropriate size at which to aggregate units but also the shape and location of the aggregated units. Various techniques have been developed to study the implications of MAUP (Openshaw, 1983), and it is an ongoing issue for researchers.

Phenomenon Scale

Phenomenon scale refers to the size at which geographic structures exist and over which geographic processes operate in the world. It is the 'true' scale of geographic phenomena. Determining the scale of phenomena is clearly a major research goal in geography. It is a common geographic dictum that scale matters. Numerous concepts in geography reflect the idea that phenomena are scale dependent or are defined in part by their scale (Meentemeyer, 1989). Vegetation stands are smaller than vegetation regions, and linguistic dialects are distributed over smaller areas than languages. The possibility that some geographic phenomena are scale independent is important, however. Patterns seen at one scale may often be observed at other scales; whether this is a matter of analogy or of the same processes operating at multiple scales is theoretically important. The mathematics of fractals has been applied in geography as a way of understanding and formalizing phenomena such as coastlines that are self-similar at different scales (Lam and Quattrochi, 1992).

The belief has often been expressed that the discipline of geography, as the study of the earth as the home of humanity, can be defined partially by its focus on phenomena at certain scales, such as cities or continents, and not other scales. The range of scales of interest to geographers is often summarized by the use of terminological continua such as 'local–global' or 'micro-, meso-, and macroscales' (Meentemeyer, 1989; Meyer et al., 1992). The view that geographers must restrict their focus to particular ranges of scales is not shared universally, however, and advances have and will continue to occur when geographers stretch the boundaries of their subject matter. Nonetheless, few would argue that subatomic or interplanetary scales are properly of concern for geography.

It is widely recognized that various scales of geographic phenomena interact, or that phenomena at one scale emerge from smaller or larger scale phenomena. This is captured by the notion of a hierarchy of scales, in which smaller phenomena are nested within larger phenomena (although the term 'nested' should not be taken to indicate that causal relations operate in only one direction, from the superordinate to the subordinate, for instance). Local economies are nested within regional economies, rivers are nested within larger hydrologic systems. Conceptualizing, measuring, and modeling such scale hierarchies can be quite difficult, and the traditional practice within geography of focusing on a single scale largely continues (Herod, 2011).

Generalization

The world can never be studied, modeled, or represented in all of its full detail and complexity. Scale is important in part because of its consequences for the degree to which geographic information is generalized. Generalization refers to the amount of detail included in information; it is essentially an issue of simplification, but also includes aspects of selection and enhancement of features of particular interest (Buttenfield and McMaster, 1991). As one studies or represents smaller pieces of the earth, one tends strongly to deal with more detailed or more fine-grained aspects of geographic features. For example, large-scale maps almost always show features on the earth's surface in greater detail than do small-scale maps; rivers appear to

meander more when they are shown on large-scale maps, for instance. Studied most extensively by cartographers, generalization is in fact relevant to all three meanings of scale, and to all three domains of spatial, temporal, and thematic scales.

Conclusion

Issues of scale have always been central to geographic theory and research. Advances in the understanding of scale and the ability to investigate scale-related problems will continue, particularly with the increasingly common representation of geographic phenomena through the medium of digital geographic information (Quattrochi and Goodchild, 1997). Cartographic scale is becoming 'visualization' scale. How is scale – whether spatial, temporal, or thematic – communicated in dynamic, multidimensional, and multimodal representations, including when visualized in virtual environments? Great progress has been made on the problem of automated generalization, programing artificial intelligence to make generalization changes in geographic data as scale changes. The ability to perform multiscale and hierarchical analysis will be developed further. More profound than these advances, however, the widespread emergence of the digital world will foster new conceptions of scale in geography, for both laypersons and specialists (Goodchild and Proctor, 1997).

Scaling and Classification in Social Measurement

This article is reproduced from the previous edition, volume 20, pp. 13504–13508, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

Every classification category is located within a taxonomy. A typology differentiates entities at a particular level of a taxonomy in terms of one or more properties. Quantitative measurements also differentiate entities at a given taxonomic level, serving like typological classifications, but obtaining greater logical and mathematical power by ordering the classification categories. Classifications ordered along a dimension of variation to provide quantitative measurements constitute a scale. Measurements and theories are interdependent for several reasons. First, taxonomies and typologies are theoretical constructions and are part of all measurements. Second, the notion of measurement error arises from the idea that theories apply to and define true values as opposed to observed values. Third, the development of meaningful measurements requires theoretical conceptualization of relations between variables, while testing a theory's validity requires adequate measurements.

Social measurements translate observed characteristics of individuals, events, relationships, organizations, societies, etc. into symbolic classifications that enable reasoning of a verbal, logical, or mathematical nature. Qualitative research and censuses together define one realm of measurement, concerned with assignment of entities to classification categories embedded within taxonomies and typologies. Another topic in measurement involves scaling discrete items of information such as answers to questions so as to produce quantitative measurements for mathematical analyses. A third issue is the linkage between social measurements and social theories.

Classifications

Classification assimilates perceived phenomena into symbolically labeled categories. Anthropological studies of folk classification systems (D'Andrade, 1995) have advanced the understanding of scientific classification systems, though scientific usages involve criteria that folk systems may not meet entirely.

Two areas of social science employ classification systems centrally. Qualitative analyses such as ethnographies, histories, case studies, etc. offer classifications – sometimes newly invented – for translating experiences in unfamiliar cultures or minds into familiar terms. Censuses of individuals, of occurrences, or of aggregate social units apply classifications – usually traditional – in order to count entities and their variations. Both types of work depend on theoretical constructions that link classification categories.

Taxonomies

Every classification category is located within a taxonomy. Some more general categorization, Y, determines which entities are in the domain for the focal categorization, X; so an X must always be a kind of Y. 'X is a kind of Y' is the linguistic frame for specifying taxonomies. Concepts constituting a taxonomy form a logic tree, with subordinate elements implying superordinate items.

Taxonomic enclosure of a classification category is a social construction that may have both theoretical and practical consequences. For example, if only violent crimes are subject to classification as homicides, then 'homicide' is a kind of 'violent crime,' and deaths caused by executive directives to release deadly pollution could not be homicides.

Typologies

A typology differentiates entities at a particular level of a taxonomy in terms of one or more of their properties. The differentiating property (sometimes called a feature or attribute) essentially acts as a modifier of entities at that taxonomic level. For example, in the United States kinship system siblings are distinguished in terms of whether they are male or female; in Japan by comparison, siblings are schematized in terms of whether they are older as well as whether they are male or female.

A scientific typology differentiates entities into types that are exclusive and exhaustive: every entity at the relevant taxonomic level is of one defined type only, and every entity is of some defined type. A division into two types is a dichotomy, into three types a trichotomy, and into more than three types a polytomy.

Polytomous typologies are often constructed by crossing multiple properties, forming a table in which each cell is a theoretical type. (The crossed properties might be referred to as variables, dimensions, or factors in the typology.) For example, members of a multiplex society have been characterized according to whether they do or do not accept the society's goals on the one hand, and whether they do or do not accept the society's means of achieving goals on the other hand; then crossing acceptance of goals and means produces a fourfold table defining conformists and three types of deviants.

Etic–emic analyses involve defining a typology with properties of scientific interest (the etic system) and then discovering ethnographically which types and combinations of types are recognized in folk meanings (the emic system). Latent structure analysis statistically processes observed properties of

a sample of entities in order to confirm the existence of hypothesized types and to define the types operationally.

Aggregate Entities

Aggregate social entities such as organizations, communities, and cultures may be studied as unique cases, where measurements identify and order internal characteristics of the entity rather than relate one aggregate entity to another.

A seeming enigma in social measurement is how aggregate social entities can be described satisfactorily on the basis of the reports of relatively few informants, even though statistical theory calls for substantial samples of respondents to survey populations. The key is that informants all report on the same thing – a single culture, community, or organization – whereas respondents in a social survey typically report on diverse things – their own personal characteristics, beliefs, or experiences. Thus, reports from informants serve as multiple indicators of a single state, and the number needed depends on how many observations are needed to define a point reliably, rather than how many respondents are needed to describe a population's diversity reliably. As few as seven expert informants can yield reliable descriptions of aggregate social entities, though more are needed as informants' expertise declines (Romney et al., 1986). Informant expertise correlates with greater intelligence and experience (D'Andrade, 1995) and with having a high level of social integration (Thomas and Heise, 1995).

Relations

Case grammar in linguistics defines events and relationships in terms of an actor, action, object, and perhaps instrumentation, setting, products, and other factors as well. Mapping sentences (Shye et al., 1994) apply the case grammar idea with relatively small lists of entities in order to classify relational phenomena within social aggregates. For example, interpersonal relations in a group can be specified by pairing group members with actions such as loves, admires, annoys, befriends, and angers. Mapping sentences defining the relations between individuals or among social organizations constitute the measurement model for social network research (Watts, 2004).

Scaling

Quantitative measurements differentiate entities at a given taxonomic level – serving like typological classifications, but obtaining greater logical and mathematical power by ordering the classification categories.

An influential conceptualization (Stevens, 1951) posited four levels of quantification in terms of how numbers relate to classification categories. *Nominal* numeration involves assigning numbers arbitrarily simply to give categories unique names, such as 'batch 243.' An *ordinal* scale's categories are ordered monotonically in terms of greater-than and less-than, and numbering corresponds to the rank of each category. Numerical ranking of an individual's preferences for different foods is an example of ordinal measurement. Differences between categories can be compared in an *interval* scale, and numbers applied to categories reflect degrees of differences. Calendar dates are an example of interval measurements – we know from their birth years that William Shakespeare was closer in time to Geoffrey Chaucer than Albert Einstein was to Isaac Newton. In a *ratio* scale, categories have magnitudes that are whole or fractional multiples of one another, and numbers assigned to the categories represent these magnitudes. Population sizes are an example of ratio measurements. Knowing the populations of both nations, we can say that Japan is at least 35 times bigger than Jamaica.

A key methodological concern in psychometrics (Hopkins, 1998) has been: how do you measure entities on an interval scale given merely nominal or ordinal information?

Scaling Dichotomous Items

Nominal data are often dichotomous yes–no answers to questions, a judge's presence–absence judgments about the features of entities, an expert's claims about truth–falsity of propositions, etc. Answers of *yes, present, true*, etc. typically are coded as 'one' and *no, absent, false*, etc. as 'zero.' The goal, then, is to translate zero–one answers for each case in a sample of entities into a number representing the case's position on an interval scale of measurement.

The first step requires identifying how items relate to the interval scale of measurement in terms of a graph of the items' characteristic curves. The horizontal axis of such a graph is the interval scale of measurement, confined to the practical range of variation of entities actually being observed. The vertical axis indicates probability that a specific dichotomous item has the value one for an entity with a given position on the interval scale of measurement. An item's characteristic curve traces the changing probability of the item having the value one as an entity moves from having a minimal value on the interval scale to having the maximal value on the interval scale.

Item characteristic curves have essentially three different shapes corresponding to three different formulations about how items combine into a scale.

Spanning items have characteristic curves that essentially are straight lines stretching across the range of entity variation. A spanning item's line may start as a low probability value and rise to a high probability value, or fall from a high value to a low value. A rising line means that the item is unlikely to have a value of one with entities having a low score on the interval scale; the item is likely to have a score of one for entities having a high score on the interval scale; and the probability of the item being valued at one increases regularly for entities between the low and high positions on the scale.

Knowing an entity's value on any one spanning item does not permit assessing the entity's position along the interval scale. However, knowing the entity's values on multiple spanning items does allow an estimate of positioning to be made. Suppose heuristically that we are working with a large number of equivalent spanning items, each having an item characteristic curve that starts at probability 0.00 at the minimal point of the interval scale, and rises in a straight line to probability 1.00 at the maximal point of the interval scale. The probability of an item being valued at one can be estimated from the observed proportion of all these items that are valued at one, which is simply the mean item score when items are scored zero–one.

Then we can use the characteristic curve for the items to find the point on the interval scale where the entity must be positioned in order to have the estimated item probability. This is the basic scheme involved in construction of *composite scales*, where an averaged or summated score on multiple items is used to estimate an entity's interval-scale value on a dimension of interest (Lord and Novick, 1968; Martinez-Martin, 2010).

The more items that are averaged, the better the estimate of an entity's position on the interval scale. The upper bound on number of items is pragmatic, determined by how much precision is needed and how much it costs to collect data with more items. The quality of the estimate also depends on how ideal the items are in terms of having straight-line characteristic curves terminating at the extremes of probability. Irrelevant items with a flat characteristic curve would not yield an estimate of scale position no matter how many of them are averaged, because a flat curve means that the probability of the item having a value of one is uncorrelated with the entity's position on the interval scale. Inferences are possible with scales that include relevant but imperfect items, but more items are required to achieve a given level of precision, and greater weight needs to be given to the more perfect items.

Declivitous items have characteristic curves that rise sharply at a particular point on the horizontal axis. Idealized, the probability of the item having a value of one increases from 0.00 to the left of the inflection point to 1.00 to the right of the inflection point; or alternatively the probability declines from 1.00 to 0.00 in passing the inflection point. Realistically, the characteristic curve of a declivitous item is S-shaped with a steep rise in the middle and graduated approaches to 0.00 at the bottom and to 1.00 at the top.

The value of a single declivitous item tells little about an entity's position along the interval scale. However, an inference about an entity's scale position can be made from a set of declivitous items with different inflection points, or difficulties that form a *cumulative scale*. Suppose heuristically that each item increases stepwise at its inflection point. Then for an entity midway along the horizontal axis, items at the left end of the scale will all have the value of one, items at the right end of the scale will all have the value zero, and the entity's value on the interval scale is between the items with a score of one and the items with a score of zero.

If the items' inflection points are evenly distributed along the interval scale, then the sum of items' zero–one scores for an entity constitutes an estimate of where the entity is positioned along the interval scale. That is, few of the items have a value of one if the entity is on the lower end of the interval scale, and many of the items are valued at one if the entity is at the upper end of the interval scale. This is the basic scheme involved in Guttman scalogram analysis (e.g., see Shye, 1978: Part 5). On the other hand, we might use empirical data to estimate the position of each item's inflection point on the interval scale, while simultaneously estimating entity scores that take account of the item difficulties. This is the basic scheme involved in scaling with Rasch models (Andrich, 1988; Engelhard, 2008).

Entities' positions on the interval scale can be pinned down as closely as desired through the use of more declivitous items with inflection points spaced closer and closer together. However, adding items to achieve more measurement precision at the low end of the interval scale does not help at the middle or the high end of the interval scale. Thus, obtaining high precision over the entire range of variation requires a large number of items, and it could be costly to obtain so much data. Alternatively, one can seek items whose characteristic curves rise gradually over a range of the interval scale such that sequential items on the scale have overlapping characteristic curves, whereby an entity's position along the interval scale is indicated by several items.

Regional items have characteristic curves that rise and fall within a limited range of the interval scale. That is, moving an entity up the interval scale increases the probability of a particular item having a value of one for a while, and then decreases the probability after the entity passes the characteristic curve's maximum value. For example, in a scale measuring prejudice toward a particular ethnic group, the probability of agreeing with the item 'they require equal but separate facilities' increases as a person moves away from an apartheid position, and then decreases as the person moves further up the scale toward a nondiscriminatory position. A regional item's characteristic curve is approximately bell-shaped if its maximum is at the middle of the interval scale, but characteristic curves at the ends of the scale are subject to floor and ceiling clipping, making them look like declivitous items.

If an entity has a value of one on a regional item, then the entity's position along the interval scale is known approximately, since the entity must be positioned in the part of the scale where that item has a nonzero probability of being valued at one. However, a value of zero on the same item can result from a variety of positions along the interval scale and reveals little about the entity's position. Thus, multiple regional items have to be used to assess positions along the whole range of the scale. The items have to be sequenced relatively closely along the scale with overlapping characteristic curves so that no entity will end up in the noninformative state of having a zero value on all items.

One could ask judges to rate the scale position of each item, and average across judges to get an item score; then, later, respondents can be scored with the average of the items they accept. This simplistic approach to regional items was employed in some early attempts to measure social attitudes. Another approach is statistical unfolding of respondents' choices of items on either side of their own positions on the interval scale in order to estimate scale values for items and respondents simultaneously (Coombs, 1964).

Item analysis is a routine aspect of scale construction with spanning items, declivitous items, or regional items. One typically starts with a notion of what one wants to measure, assembles items that should relate to the dimension, and tests the items in order to select the items that work best. Since a criterion measurement that can be used for assessing item quality typically is lacking, the items as a group are assumed to measure what they are supposed to measure, and scores based on this assumption are used to evaluate individual items.

Items in a scale are presumed to measure a single dimension rather than multiple dimensions. Examining the dimensionality assumption brings in additional technology, such as component analysis or factor analysis in the case of spanning items, multidimensional scalogram analysis in the case of declivitous items, and nonmetric multidimensional scaling in the case of regional items. These statistical methods help in

refining the conception of the focal dimension and in selecting the best items for measuring that dimension.

Ordered Assessments

Ordinal data, the starting point for a three-volume mathematical treatise on measurement theory (Krantz et al., 1971; Suppes et al., 1989; Luce et al., 1990), may arise from individuals' preferences, gradings of agreement with statements, reckonings of similarity between stimuli, etc. Conjoint analysis (Luce and Tukey, 1964; Michell, 1990; Green et al., 2001) offers a general mathematical model for analyzing such data. According to the conjoint theory of measurement, positions on any viable quantitative dimension are predictable from positions on two other quantitative dimensions, and this assumption leads to tests of a dimension's usefulness given just information of an ordinal nature. For example, societies might be ranked in terms of their socioeconomic development and also arrayed in terms of the extents of their patrifocal technologies (like herding) and matrifocal technologies (like horticulture), each of which contributes additively to socioeconomic development. Conjoint analyses could be conducted to test the meaningfulness of these dimensions, preliminarily to developing interval scales of socioeconomic development and patrifocal and matrifocal technologies. Specific scaling methodologies, like Rasch scaling and nonmetric multidimensional scaling, can be interpreted within the conjoint analysis framework.

Magnitude estimations involve comparisons to an anchor, for example: "Here is a reference sound. … How loud is this next sound relative to the reference sound." Trained judges using such a procedure can assess intensities of sensations and of a variety of social opinions on ratio scales (Stevens, 1951; Lodge, 1981). Comparing magnitude estimation in social surveys to the more common procedure of obtaining ratings on category scales with a fixed number of options, Lodge (1981) found that magnitude estimations are more costly but more accurate, especially in registering extreme positions.

Rating scales with bipolar adjective anchors like good–bad are often used to assess affective meanings of perceptions, individuals, events, etc. Such scales traditionally provided seven or nine answer positions between the opposing poles with the middle position defined as neutral. Computerized presentations of such scales with hundreds of rating positions along a graphic line yield greater precision by incorporating some aspects of magnitude estimation. Cross-cultural and cross-linguistic research in dozens of societies has demonstrated that bipolar rating scales align with three dimensions – evaluation, potency, and activity (Osgood et al., 1975). An implication is that research employing bipolar rating scales should include scales measuring the standard three dimensions in order to identify contributions of these dimensions to rating variance on other bipolar scales.

Measurements and Theory

Theories and measurements are bound inextricably. In the first place, taxonomies and typologies, which are theoretical constructions, even when rooted in folk classification systems, are entailed in defining which entities are to be measured, so are part of all measurements.

Second, scientists routinely assume that any particular measurement is wrong to some degree, even a measurement based on a scale, and that combining multiple measurements improves measurement precision. The underlying premise is that a true value exists for that which is being measured, as opposed to observed values, and that theories apply to true values, not ephemeral observed values. In essence, theories set expectations about what should be observed, in contrast to what is observed, and deviation from theoretical expectations is interpreted as measurement error (Kyburg, 1992). A notion of measurement error as deviation from theoretical expectations is widely applicable, even in qualitative research (McCullagh and Behan, 1984; Heise, 1989).

Third, the conjoint theory of measurement underlying many current measurement technologies requires theoretical specification of relations between variables before the variables' viability can be tested or meaningful scales constructed. This approach is in creative tension with traditional deductive science, wherein variable measurements are gathered in order to determine if relations among variables exist and theories are correct. In fact, a frequent theme in social science during the late twentieth century was that measurement technology had to improve in order to foster the growth of more powerful theories. It is clear now that the dependence between measurements and theories is more bidirectional than was supposed before the development of conjoint theory.

This article is a revision of the previous edition article by R. Warner, volume 20, pp. 13530–13537, © 2001, Elsevier Ltd.

Abstract

Schizophrenia is a severe mental disorder characterized by a combination of symptoms including delusions, hallucinations, and disorganized thinking with disease onset in early adulthood. Diagnostic criteria include the typical clinical symptoms, a minimum duration of symptoms, and the exclusion of other causes of psychotic disorders like brain inflammation or the use of illicit drugs. While some persons with schizophrenia have a mild disease course with single episodes, the majority will have a chronic disease course with repeated episodes and/or increasing functional impairments. Treatment is mainly with antipsychotic medication. Manualized psychotherapeutic approaches are becoming available.

Definitions

Schizophrenia is defined as a mental disorder characterized by psychotic symptoms (delusions, hallucinations, thought disorder) of a certain duration occurring in the absence of other recognizable causes of psychotic disorders like several general somatic disorders, substance use, or withdrawal of substances of addiction. As schizophrenia occurs in the absence of other known general or mental disorders that may lead to psychotic symptoms, schizophrenia is considered a 'primary' psychotic disorder. The psychotic disorders occurring due to brain or general somatic disorders are 'secondary' psychotic disorders. An example of the latter would be the occurrence of psychotic symptoms in a patient with epilepsy or in a state of delirium, in which the psychotic symptoms remit once the underlying general medical condition is normalized. Note that the definition used here to denote 'psychosis' (the occurrence of delusions, hallucinations, and/or a thought disorder) is a rather narrow definition. The concept of 'psychosis' has undergone considerable changes over time, but its core symptoms are the above-mentioned symptoms regardless of their causes (Beer, 1996).

Intellectual Backgrounds, Including Schools of Thought and Leading Advocates

The concept of a dichotomy between primary psychotic disorders having a poor prognosis leading to rapid clinical deterioration ('dementia praecox,' where 'dementia' does not indicate the dementia as outlined in the modern classification systems of brain disorders, but rather a mental disorder with severe clinical symptoms and a poor prognosis) and those with a good prognosis (manic-depressive illnesses) had been introduced by Emil Kraepelin (Palm and Möller, 2011). The Swiss psychiatrist E. Bleuler reformulated Kraepelin's concept of 'dementia praecox' and introduced the term 'schizophrenia' (Bleuler, 1908). The clinical picture of schizophrenia in Bleuler's sense was characterized by four basic symptoms, i.e., formal thought disorder, affect disorder, a lack of drive, and autism. Bleuler also added accessory symptoms, i.e., delusions, hallucinations, and catatonia, the last of these being a state of severe psychomotor disturbances characterized, among other clinical features, by an increased muscle tone. Kurt Schneider in 1938 revised the hierarchical order of these symptoms by differentiating first-rank symptoms and second-rank symptoms (Table 1).

These three schools of thinking (Kraepelin, Bleuler, Schneider) were the major influences when the modern classification criteria for mental disorders were developed: for the International Classification of Mental Disorders (ICD) published by the World Health Organization (WHO) (now in its 10th revision, hence ICD-10; World Health Organization, 1992) and the Diagnostic and Statistical Manual (DSM) published by the American Psychiatric Association (now in its fifth revision, hence DSM-5; American Psychiatric Association, 2013). These classification systems retained the dichotomy of schizophrenia-like and manic-depressive psychotic illnesses.

Regarding nomenclature, the term 'schizophrenia' has been substituted in several countries due to its stigmatizing connotations (e.g., now 'integration disorder' in Japan; Sato, 2006). In Japan, this renaming was accompanied by a paradigm shift in the concept of the disorder toward a manageable – as opposed to the previous concept of an intractable – mental disorder. There are two major issues concerning the concept of schizophrenia, which have been debated since the initial concept was introduced by Bleuler: (1), is schizophrenia

Table 1 First-rank symptoms of schizophrenia according to K. Schneider (English translation: 1959)

- Auditory hallucinations
  - Voices heard arguing or giving instructions (second person)
  - Voices heard commenting on one's actions (running commentary, usually describing the patient in the third person)
- Somatic/thought passivity experiences (delusions of control/of being controlled)
- Thought echo (thoughts being heard aloud)
- Thought withdrawal
- Thought insertion (thoughts are ascribed to other people who are intruding into the patient's mind)
- Thought broadcasting (also called thought diffusion)
- Delusional perception (linking a normal sensory perception to a bizarre conclusion, e.g., seeing an airplane means the patient is the president)

a nosologically distinct mental disorder or rather a collection of different mental disorders with similar clinical and course characteristics (the latter defining a 'group of schizophrenias') and (2) what are the causes of schizophrenia. Since the latter is the question underlying the first issue, the authors attend to the question in some detail in the following article.

Current Knowledge

Currently, the pathophysiology of schizophrenia is unknown. A diagnosis of schizophrenia can be made if the appropriate psychotic symptoms are present, the necessary duration criterion is fulfilled, and other medical reasons for the occurrence of psychotic symptoms have been excluded. Thus, schizophrenia is a clinical diagnosis arrived at by careful clinical investigation, history taking, and additional diagnostic procedures like neuroimaging if necessary to exclude other medical conditions.

Schizophrenia may take different courses. About one-third of all cases are self-limiting, single episodes. In another one-third of the cases, recurrent episodes are characteristic with intervening complete or incomplete symptom remission. A final third of cases has a chronic progressive disease course with increasing and enduring symptoms and disability, with occasional acute psychotic exacerbations (**Figure 1**). Thus, first-episode schizophrenia patients in one-third of the cases have a comparatively good prognosis, while two-thirds will experience a chronic disease course (Ram et al., 1992). Functional impairments are especially prominent during acute psychotic episodes in all three disease course types due to 'positive' symptoms like delusions or hallucinations. In the chronic progressive course type, 'negative' symptoms like lack of drive or attentional deficits, and cognitive symptoms like memory impairments, become additional causes of functional impairment.

Figure 1 Disease course characteristics of schizophrenia. In schizophrenia, three major disease types can be distinguished. Upper panel: single lifetime episode. Middle panel: repeated episodes with complete symptom remission between episodes. In some cases, there is only incomplete symptomatic remission between episodes (dotted line). Lower panel: chronic progressive schizophrenia with superimposed episodes.

Epidemiology, Illness-Associated Factors and Burden of Disease

Schizophrenia usually begins with unspecific prodromal symptoms in late adolescence, and such prodromal symptoms like a lack of drive or concentration problems may lead to problems in school or in social relationships. Men seem to be at a slightly higher risk for first-episode psychosis and tend to be younger at onset. The diagnosis of schizophrenia is only made once a full clinical psychotic picture has developed. The lifetime prevalence of schizophrenia worldwide is around 1% with little regional variation or change over time (Jablensky, 1997), with prevalence rates using DSM-III and later criteria being somewhat lower due to more restrictive criteria compared to earlier classification criteria (after DSM-III around 0.7%; Bromet and Fennig, 1999). The annual incidence rate is about 0.2/1000. There is a strong aggregation of schizophrenia within affected families, with the highest rates reported for monozygotic twins (around 50%), followed by children with two parents with schizophrenia (46%), dizygotic twins (15%), and children with one parent having schizophrenia (12.8%) (Bromet and Fennig, 1999). There is an epidemiological association between urbanicity and schizophrenia, but it is unknown whether this is a causal association. Other, weaker associations were described for obstetric, birth, and early childhood complications. The disease burden caused by schizophrenia is considerable since approximately two-thirds of patients with schizophrenia have chronically progressive or chronically relapsing-remitting disease course types with ensuing chronic functional impairments. The 1-year functional outcome is favorable in about half of all schizophrenia patients and is associated with a short duration of untreated psychosis, rapid response toward treatment, low total symptom load, younger age, female gender, good premorbid social adjustment, and employment (Spellmann et al., 2012). In persons with chronic schizophrenia, high degrees of mental health care and other social services utilization are observed leading to high societal costs (Ekman et al., 2013; Mangalore and Knapp, 2007). In a European survey of costs for mental and neurological disorders, psychotic disorders (including schizophrenia) were ranked third following dementia and mood disorders (Gustavsson et al., 2011). While hospital costs are a major contributor to the societal costs of schizophrenia, analyses also show that replacing inpatient treatment by outpatient treatment will not reduce total costs (Mangalore and Knapp, 2007) and that non-healthcare-related factors like loss of productivity come into play. A special issue is related to the epidemiology and mental health care of schizophrenia in low-income countries. While the prevalence appears to be similar worldwide, there are indications that the functional outcome is better in low-income countries, which may be due to better family and workplace-related support compared to that in high-income countries (Naheed et al., 2012). However, this viewpoint is currently debated and there are also indication

of undertreatment, neglect, and human rights violations in developing countries warranting further investigations (Patel et al., 2006).

Diagnosis and Classification

Both major international classification systems for mental disorders, DSM-5 and ICD-10, include a category 'schizophrenia.' The diagnostic criteria are summarized in **Table 2** and include lists of symptoms that may be present, exclusion criteria, and duration criteria. Due to the differences in details of the diagnostic criteria in both systems, a person diagnosed with schizophrenia following the guidelines of one classification system may not fulfill the criteria of the other system, or vice versa. Such distinguishing differences are, for example, the different duration criteria and the different symptom lists. Also, ICD-10 does not require social or occupational dysfunction, as DSM-5 does, for establishing a diagnosis of schizophrenia.

The ICD-10 is currently under revision and proposals for revised schizophrenia criteria have been put forward by the WHO working group on psychotic disorders (Gaebel et al., 2013). These would lead to a harmonization of the course criteria with DSM-5, but would retain the different duration criteria. Similar to DSM-5, ICD-11 would deemphasize

Table 2 Comparison of the diagnostic criteria of schizophrenia in DSM-5 (American Psychiatric Association, 2013) and ICD-10 (World Health Organization, 1992)

Criterion	*DSM-5*	*ICD-10*
Clinical symptoms	Two (or more) of the following, each present for a significant portion of time during a 1-month period (or less if successfully treated). At least one of these must be (1), (2), or (3): 1. Delusions 2. Hallucinations 3. Disorganized speech (e.g., frequent derailment or incoherence) 4. Grossly disorganized or catatonic behavior 5. Negative symptoms (i.e., diminished emotional expression or avolition)	One very clear symptom (and usually two or more if less clear-cut) belonging to any one of the following groups listed as (1) to (2), or symptoms from at least two of the groups (5) to (8): 1. Thought echo, thought insertion or withdrawal, and thought broadcasting 2. Delusions of control, influence, or passivity, clearly referred to body or limb movements or specific thoughts, actions, or sensations; delusional perception 3. Hallucinatory voices giving a running commentary on the patient's behavior, or discussing the patient among themselves, or other types of hallucinatory voices coming from some part of the body 4. Persistent delusions of other kinds that are culturally inappropriate and completely impossible, such as religious or political identity, or superhuman powers and abilities (e.g., being able to control the weather, or being in communication with aliens from another world) 5. Persistent hallucinations in any modality, when accompanied either by fleeting or half-formed delusions without clear affective content, or by persistent overvalued ideas, or when occurring every day for weeks or months on end 6. Breaks or interpolations in the train of thought, resulting in incoherence or irrelevant speech, or neologisms 7. Catatonic behavior, such as excitement, posturing, or waxy flexibility, negativism, mutism, and stupor 8. Negative' symptoms such as marked apathy, paucity of speech, and blunting or incongruity of emotional responses, usually resulting in social withdrawal and lowering of social performance; it must be clear that these are not due to depression or neuroleptic medication 9. A significant and consistent change in the overall quality of some aspects of personal behavior, manifest as loss of interest, aimlessness, idleness, a self-absorbed attitude, and social withdrawal
Functional impairments	Social/occupational dysfunction	None required
Duration	6 months	1 month
Exclusion	Schizoaffective and mood disorder exclusion Substance/general medical condition exclusion No relationship to a pervasive developmental disorder	

Schneiderian first-rank symptoms and would introduce severity/symptom specifiers.

Treatment

Treatment is based on the three pillars: pharmacotherapy, psychotherapy, and social therapy. Guidelines for schizophrenia treatment have been developed worldwide, but differ in the details of their therapeutic recommendations reflecting different interpretation of clinical study results, different therapeutic traditions, and different approaches toward mental health care in general (Gaebel et al., 2011). Yet, some treatment principles are common ground: during the acute psychotic phase, antipsychotic medication is usually indicated to shorten the psychotic episode (Hasan et al., 2012). Antipsychotic medication is also effective in preventing future psychotic episodes, so that a certain period of continuing antipsychotic drug therapy after an initial psychotic episode is recommended (Hasan et al., 2013a). This may need to be continued for extended periods of time if repeated episodes occur. Antipsychotic medication is especially effective in the treatment of the 'positive' symptoms of schizophrenia, i.e., hallucinations and delusions, and 90% of patients experience full or partial symptomatic remission of positive symptoms (Schennach et al., 2012). Antipsychotic pharmacotherapy is less effective in treating the 'negative' symptoms, i.e., anhedonia and lack of drive (Gaebel et al., 2014). Blunted affect is the most frequently persisting negative symptom in patients with first-episode schizophrenia and its occurrence is associated with a long duration of untreated psychosis and with treatment cessation (Galderisi et al., 2013). Alternatively or in combination with antipsychotic pharmacotherapy, effective modes of cognitive psychotherapy are now available for schizophrenia patients. Cognitive psychotherapy was shown to be effective for the treatment of positive and negative symptoms, but different psychotherapeutic programs are needed. Cognitive remediation therapy was shown to be effective in the treatment of cognitive dysfunctions in schizophrenia.

One of the controversial issues in schizophrenia treatment is the differential indication for 'first'- or 'second'-generation antipsychotic drugs. While both are equally effective in treating positive symptoms, the 'first-generation antipsychotic drugs' are considered problematic because of their frequent side effects on motor functions like gait. Second-generation antipsychotic drugs are viewed by some as better able to treat negative symptoms, but this opinion is debated. It is currently also debated whether second-generation antipsychotic drugs produce less motor side effects compared to first-generation antipsychotic drugs. These potential advantages of second-generation antipsychotic drugs need to be viewed in the light of increased rates of metabolic side effects in second-generation antipsychotic drugs, e.g., on glucose homeostasis. Guideline recommendations as to a preference for first- or second-generation drugs are divergent and it is therefore recommended to decide on which antipsychotic drug to use in individual persons depending on the availability of each drug in the respective country, patient preferences, side effect profiles, and practitioner's familiarity and experiences with each drug.

Different stages of the disease may demand different treatment strategies. In the first episode of schizophrenia, initial antipsychotic treatment accompanied by psychotherapy and sociotherapy, the latter involving rehabilitation to gain or regain education and/or employment, will usually be indicated. Methods of art therapy, sports therapy, and specially structured rehabilitation programs may also be added. It is recommended to continue antipsychotic therapy for at least 2 years following the initial psychotic episode. If new episodes occur, a relapsing disease course must be assumed and longer periods of prophylactic antipsychotic medications are warranted, e.g., for 5 years or even lifelong. In such cases, depot drug formulations may be warranted. However, the question of maintenance therapy is still controversial in the guidelines regarding the necessary duration and strategies for changing antipsychotic therapy in treatment-refractory cases (Takeuchi et al., 2012). If negative symptoms become dominant, especially in the chronic progressive forms of schizophrenia, psychotherapy and sociotherapy take centerstage because the negative symptoms would not be expected to respond well to antipsychotic pharmacotherapy. However, the latter should be continued with a view to prevent acute psychotic exacerbations. Little is known about schizophrenia of persons with greater ages. In the approximately 30% of cases with chronic symptoms, negative symptoms usually prevail and may be difficult to distinguish from cognitive impairments, which may be the consequence of higher age or incipient dementing illnesses. Another open question is whether treatment guidelines developed for early-onset patients are also valid for late-onset patients, i.e., disease onset after 40 years of age, who may constitute up to approximately 25% of all schizophrenia cases. Few studies have addressed this issue and currently, no recommendations based on large-scale studies can be made (Essali and Ali, 2012). Another important issue is the availability of medication in low-income countries (Naheed et al., 2012).

Prevention

Currently, there are no known effective preventive measures against the development of schizophrenia in individual persons. The large number of involved genes leading to genetic heterogeneity, pleiotropy, and incomplete penetrance are the major factors explaining why studies with all available genetic methods (genetic polymorphisms, genome-wide association studies, copy number variation studies, studies of epigenetic factors) have so far not been able to identify genes allowing individual predictions (Addington and Rapoport, 2012). However, there is a prodromal phase of months to years with attenuated psychotic symptoms or unspecific symptoms like concentration or affective problems before the full psychotic picture emerges, and such a prodromal period is reported by 80–90% of persons with schizophrenia (Yung and McGorry, 1996). The prodromal phase offers the potential for future preventive measures like pharmacotherapy or psychotherapy. There is, however, no consensus yet about the typical clinical prodromal presentation that indicates the highest risk of incipient development of schizophrenia, since less than half of all persons who experience

prodromal symptoms continue to develop schizophrenia in the future. Research is ongoing to better define the high-risk prodromal clinical picture and to better predict the imminent development of schizophrenia in individual persons. This knowledge would be a prerequisite for employing preventive therapeutic measures, which may have severe side effects. Current pharmacological research aims at establishing safe ways of indicated or selective prevention once a high risk for the development of schizophrenia is detected in individual persons (Addington and Heinssen, 2013). Given the uncertainties surrounding the prodromal phase of schizophrenia, DSM-5 has only defined an 'attenuated psychosis syndrome' as a mental state requiring further research, but not as a full psychotic disorder entity (Tsuang et al., 2013).

Changes in Focus or Emphasis over Time

With the introduction of rigorous clinical research methods in psychiatry and the discovery of the central role of dopamine neurotransmitter alterations in the pathophysiology of schizophrenia, clinical schizophrenia research initially (i.e., in the second half of the past century) was focused on the development of antidopaminergic drugs for the treatment of schizophrenia. This led to the development of the antipsychotic drugs still in use today. From the 1960s to the 1970s, research into social and environmental causes of schizophrenia took centerstage showing associations with prebirth viral infections and urbanicity. Starting in the late twentieth century, research into the role of cognitive dysfunctions in schizophrenia gained considerable momentum following the findings that social cognition and neurocognition play an important role in determining everyday functioning in persons with schizophrenia (Mehta et al., 2013), that cognitive dysfunctions are amenable to treatment (Saperstein and Kurtz, 2013), and that cognitive therapy improves the outcome of work rehabilitation in schizophrenia (Kurzban et al., 2010). The turn of the century was characterized by increased research into the genetic associations of schizophrenia, leading not only to the discovery of a plethora of genetic alterations in persons with schizophrenia but also to the result that these were not able to fully explain the clinical picture. However, many of the genes shown to be associated with schizophrenia were identified as genes of neural structures or functions, providing new impetus to cranial neuroimaging and neurophysiological investigations in schizophrenia research. Reevaluating the available evidence, the DSM-5 work group on psychotic disorders reasoned to abolish the traditional schizophrenia subtypes (paranoid, hebephrenic, and catatonic) and to deemphasize Schneiderian first-rank symptoms by substituting them with symptom specifiers including symptoms for positive and negative symptoms and by introducing a catatonia specifier (Tandon et al., 2013a,b).

Current and Emerging Directions in Theory and Research

The interindividual phenotypic variability of the psychopathological picture of schizophrenia, the multitude of genes with only minor contributions from single genes or genetic polymorphisms to this variability, and the complexity of the clinical picture are major challenges to current schizophrenia research. These conceptual challenges also lead to considerable problems in developing appropriate animal models of psychotic disorders, beyond the general conceptual problem of ascertaining delusional or hallucinatory states in experimental animals (O'Tuathaigh et al., 2013). There is an increasing research emphasis on the biological mechanisms of the pathophysiology of schizophrenia addressing several key questions: (1) which are the neural pathways involved in the pathophysiology of schizophrenia, (2) how can environmental factors exert an influence on disease development, and (3) which different biopsychosocial mechanisms interact in the pathophysiology of schizophrenia. As regards the identification of neural pathways involved in the pathophysiology of schizophrenia, several lines of investigation have shown that there are changes in the complex structure of brain neural circuits, which may be due to dysmyelinating changes of brain fiber tracts. Considering the role of environmental influences, current research focuses on identifying epigenetic effects on the genome of affected individuals and showing how early life adverse events may carry over neurobiological effects into adolescence and adulthood. Regarding the manifold biological mechanisms, it is currently being investigated whether symptom- and not diagnosis-centered research may help to identify common pathophysiologic factors for similar symptoms occurring in different mental disorders, with a view to identify unifying pathophysiological principles.

It is becoming increasingly appreciated that the psychotic symptoms occurring in schizophrenia are not readily explained by neurobiological (neurophysiological or neurogenetic and other) mechanisms. For example, in hallucination research, novel interest focuses on the psychopathological components of a hallucinatory experience (e.g., location of hallucinations, loudness, linguistic complexity), how each of these components is determined by different neural functions, and how these functions or their interplay are disturbed in schizophrenia (Stephane, 2013). Another approach is to link genomic aberrations in at-risk persons with nongenomic (environmental) influences to demonstrate ensuing aberrant gene expression and neurobiological alterations, as, for example, excess glutamate production leading to overproduction of (psychotogenic) brain dopamine and brain structural alterations in the hippocampus of at-risk persons becoming psychotic if the situation is not ameliorated (Moghaddam, 2013). Importantly, initial research shows that the pathophysiological factors determining the transition from 'at risk' to 'schizophrenia' may be different from those sustaining chronic positive or negative symptoms (Moghaddam, 2013), leading to the concept that stage-specific pathophysiologic mechanisms may make stage-specific interventions necessary. For example, based on the findings that antidopaminergic drugs may increase glutamate release, these drugs may not be the best choice in the prodromal stages, in which research indicates that excess glutamate is a key driver of the pathophysiologic process driving the progression from prodromal to psychotic states. Also, antiinflammatory drugs like omega-3-fatty acids may be more effective in the prodromal than in the later psychotic disease stages

(Mossaheb et al., 2013). Other approaches aim at correcting disturbed neural circuitry with electric or magnetic brain stimulation techniques, but these have so far only had limited success (Hasan et al., 2013b).

Research from neuroimaging and neurophysiology using electroencephalography and highly sophisticated modeling approaches shows that there are complex disturbances of the hierarchical and temporal order of neural functions once schizophrenia has fully developed. Therefore, a new research initiative by the National Institutes of Mental Health is paradigmatic for the new neural-systems-centered, integrative approach toward explanations of the pathophysiology of mental disorders in general and of schizophrenia in particular: The Research Domain Criteria (RDoC) initiative aims to identify the disturbed neural pathways, establish assessment methods, and explain the relationship of neural dysfunctions with psychopathology (Cuthbert and Insel, 2013). Based on the many neurobiological findings in schizophrenia research, novel therapeutic and diagnostic strategies will become available, but probably not in the near future. Integrative models of schizophrenia pathophysiology are warranted to reflect and guide such future advances.

Based on such insights into the pathophysiology of schizophrenia, novel drugs are being developed, for example, drugs targeting nicotinic acetylcholine receptors (Wallace and Porter, 2011) or the neurotransmitter glutamate (Kinon and Gómez, 2013). However, drug development is slow in schizophrenia given the complex longitudinal dynamics of individual disease course patterns. This also pertains to invasive therapeutic approaches like psychosurgery or deep brain stimulation, which have been successful in other mental disorders, and which may offer benefits for the future of schizophrenia treatment (Soares et al., 2013).

Another important focus for future research will be the role of stigmatization in schizophrenia. A recent systematic review showed that more than half of all persons with schizophrenia perceive or experience stigmatization (Gerlinger et al., 2013). Stigmatization also affects psychiatry and psychiatrists (Sartorius et al., 2010). A major challenge for the future will be to define the best ways to reduce and possibly eliminate the stigmatization of persons with schizophrenia and the persons and institutions caring for persons with schizophrenia, since finding a cure for schizophrenia will only become possible once the pathophysiology of this complex and severe mental disorder has been elucidated.

Abstract

Schizophrenia is a frequent brain disorder (live time prevalence about 1.5%) of unknown origin which tends to have a chronic course and deteriorates numerous complex brain functions including thought, emotion, perception, cognition, and behavior. There is no cure for schizophrenia, but the combined administration of pharmacological and psychosocial interventions yields considerable benefit for the patients affected. The targets of treatment are positive symptoms (e.g., hallucinations and delusions) and negative ones (e.g., affective flattening, anhedonia). Antipsychotic drugs (also called neuroleptic drugs) are particularly effective against negative symptoms, probably by influencing neurotransmitter systems within the central nervous system, such as dopaminergic and serotoninergic systems. Psychosocial interventions, which among others include educational programs, social-skill and problem solving training, and supervised residential living arrangements, improve to some extent negative symptoms and social integration. Recent developments and future directions of treatment include the successful pharmacological targeting of negative symptoms, the use of pharmacogenetic strategies to improve treatment response, and the development of drugs directed toward various physiological systems which are supposed to play a pathophysiological role, such as glutamatergic neurotransmission, the immune system, and phospholipid metabolism.

Introduction

Schizophrenia is a brain disorder of unknown origin which severely deteriorates numerous complex functions of the central nervous system including thought, emotion, perception, cognition, and behavior. Schizophrenia is one of the most debilitating psychiatric disorders. Due to the high lifetime prevalence (about 1.5%), the typical onset in early adulthood, and the strong tendency toward a chronic course, the disorder requires a very high degree of health care provisions. About one-quarter of hospital beds are occupied by schizophrenic patients, and the total costs of treatment are enormous (e.g., US$50 billion per year in the United States). Although there is no cure for schizophrenia, the combined administration of pharmacological and psychosocial interventions considerably improves outcome, enhances quality of life in the patients affected, and enables social integration to a large extent.

Causes and Pathophysiology of Schizophrenia

The causes of schizophrenia are unknown so far. Therefore, the term 'schizophrenia' refers to an empirically defined syndrome characterized by a combination of certain symptoms which occur in a particular temporal pattern. The idea that schizophrenia is a distinct brain disorder is rooted in Emil Kraepelin's concept of dementia praecox (Kraepelin, 1910). This concept emphasized one particular aspect of the disorder: the onset of persistent cognitive disturbances early in life. The term 'schizophrenia' was coined by Eugen Bleuler (1916), who wanted to emphasize the loss of coherence between thought, emotion, and behavior which represents another important feature of the disorder. Bleuler actually spoke about 'schizophrenias,' implying a group of diseases rather than one distinct disease entity. The present diagnostic systems compiled by the World Health Organization (*ICD-10* 1992) and the American Psychiatric Association (*DSM-IV* 1994) distinguish various subtypes of schizophrenia (see **Table 1**) which are classified according to particular symptom combinations, and according to certain aspects of the course and prognosis of the disease. However, these subtypes are defined in a phenomenological manner which neither implies distinct causes for any of the subtypes nor any particular treatment.

Although we do not know individual causes of schizophrenia, we know that the basis for the disorder is an interaction between genetic susceptibility factors and environmental components. According to numerous genetic studies the estimates of hereditability converge to about 80% (Owen and Cardno, 1999). However, although linkage studies have yielded evidence for a number of susceptibility loci on various chromosomes, neither a single gene nor a combination of genes have been discovered so far which are definitively involved. Similarly, a number of environmental factors (e.g., birth and pregnancy complications, viral infections) are likely to play a role, but details of this role remain to be established.

Although the symptoms of schizophrenia clearly demonstrate a severe disturbance of brain functions, only subtle alterations of brain morphology have been detected. The most

Table 1 Subtypes of schizophrenia according to the major classification systems

stable finding is a slight enlargement of brain ventricles. Recent sophisticated studies combining morphological and functional brain imaging have been suggested to indicate that subtle structural or functional lesions particularly in prefrontal and limbic neural circuits impair the integrity of these circuits (Andreasen et al., 1998). Although it is still a matter of debate whether these lesions are due to a neurodevelopmental or a neurodegenerative process (Lieberman, 1999), it is clear that disturbed functioning of neuronal circuits goes along with altered neurotransmission. Dopamine, serotonin, and glutamate are the neurotransmitters most frequently implicated in the pathophysiology of schizophrenia. However, it is still not clear whether disturbed neurotransmission is the cause or the consequence of the major disease process.

Due to this scantiness of etiological and pathophysiological knowledge, the treatment of patients suffering from schizophrenia is based exclusively on empirical clinical knowledge. As outlined in detail below, the treatment approach is multimodal and based on the symptom patterns present in any individual patient (*see* Mental Illness, Etiology of).

Symptoms of Schizophrenia – the Targets for Treatment

Schizophrenia affects almost all areas of complex brain functions, and thought, perception, emotion, cognition, and behavior in particular. There have been numerous approaches to systematize the plethora of symptoms according to a variety of theoretical concepts. One widely accepted concept is the distinction between positive and negative symptoms (Andreasen et al., 1995, **Table 2**) (*see* Psychiatric Assessment: Negative Symptoms). This approach groups symptoms according to whether they represent a loss of or a deficiency in a normal brain function (negative symptoms) or the appearance of abnormal phenomena (positive symptoms). From the perspective of treatment the positive–negative dichotomy is of importance because these two domains react somewhat differently to treatment. In general, positive symptoms respond fairly well to treatment with antipsychotic drugs, whereas negative symptoms are rather difficult to influence. The latter is particularly problematic, because negative symptoms are usually the limiting factor for personal and social rehabilitation. In addition to the typical symptoms, patients suffering from schizophrenia often present numerous other psychiatric problems. Among these, anxiety, sleep disturbances, obsessions and compulsions, depression and drug or substance abuse are particularly frequent. Although these additional symptoms and problems may in many cases be the consequence of the typical symptoms rather than signs of independent additional psychiatric disorders, they complicate the course of the disease and often necessitate specific treatment approaches.

Table 2 Positive and negative symptoms of schizophrenia. Areas of symptoms are listed and selected examples appear in parentheses

Positive symptoms
Hallucinations (*auditory, somato-tactile, visual, olfactory*)
Delusions (*persecutory, religious, thought broadcasting, thought insertion*)
Bizarre behavior (*unusual clothing or appearance, repetitive, stereotyped behavior*)
Positive formal thought disorders (*incoherence, illogicality, tangentiality*)
Negative symptoms
Affective flattening (*unchanging facial expression, paucity of expressive gestures*)
Alogia (*poverty of speech, increased response latency*)
Avolition-apathy (*physical anergia, problems with personal hygiene*)
Anhedonia-asociality (*reduction in social activities, sexual interest, closeness*)
Attention (*social inattentiveness, inattentiveness during testing*)

The course of schizophrenia varies considerably between patients. Typically, the disease begins during early adulthood with the appearance of rather unspecific negative symptoms resulting in social withdrawal and impaired social and scholastic adjustment. Months to years later positive symptoms such as delusions and hallucinations appear either gradually or abruptly. Across time, positive symptoms tend to show an episodic course, whereas negative symptoms either remain quite stable or even progress. The associated psychiatric problems mentioned above do not show any systematic temporal relationship to the course of schizophrenia itself. Since the syndrome of schizophrenia has been defined, data on the final outcome have varied considerably, depending mainly on the diagnostic concepts applied. There is no doubt that full remission occurs, but probably in less than 20% of patients. In the majority of patients schizophrenia takes a chronic course (Schultz and Andreasen, 1999). The major benefit from modern treatment strategies is probably not a substantial increase in the rate of full remissions, but a significant reduction in the number of extremely ill patients, and in the severity and number of episodes characterized by prominent positive symptoms.

The Principles of Treatment

Treatment of schizophrenia is usually multimodal and comprises approaches from two major areas, which are drug treatment and psychosocial interventions. In general, appropriate drug treatment is a prerequisite for the ability of the patients to comply with and actively take part in psychosocial treatments. The more effective drug treatment is, the more specialized and sophisticated psychosocial interventions can be successfully applied. Vice versa, appropriate psychosocial treatment considerably improves the compliance with drug treatment, because it enhances insight into the disease process, which initially is poor in many patients suffering from schizophrenia.

Antipsychotic drugs (also called neuroleptics) are the most important and most effective therapeutic weapon. The major targets of these drugs are positive symptoms, although newer substances might also reduce negative symptoms to some extent (see below). Treatment with antipsychotic drugs is usually a long-term treatment, whereas drugs to control accessory symptoms (anxiolytics, hypnotics, and antidepressants) are prescribed intermittently when needed. The use of electroconvulsive therapy was widespread before antipsychotic

drugs were available, but today is very limited, although this treatment is effective in certain conditions (Fink and Sackeim, 1996).

Among the psychosocial interventions, supportive and psychoeducative approaches are feasible for the majority of patients, whereas structured social skill training, family therapy, or complex programs including cognitive-behavioral therapies require a considerable degree of insight and compliance. Although recent psychosocial treatment approaches incorporate also psychodynamic aspects, classical psychodynamic psychotherapy, in general, is not effective and sometimes even counterproductive.

Prior to the discovery of antipsychotic drugs, most schizophrenic patients had been hospitalized for decades or even for their entire life. Today, very differentiated treatment facilities are available, which to a large extent are community based. These include, besides classical hospitals and outpatient departments, short-term crisis intervention facilities, day-time clinics, and supported living facilities. This network of facilities considerably increases the chance for social integration and reduces the time spent overall in hospitals. However, recent aggressive approaches to shorten the duration of hospital stays dramatically might lead to a high frequency of rehospitalization, poor long-term outcome, and an overall increase in the costs of treatment.

An important limiting factor for all treatment approaches is the patients' compliance. In particular in severely ill patients compliance is often poor. In schizophrenia noncompliance is particularly due to a lack of insight into the fact of being ill, reduced ability to actively take part in the treatment process due to negative symptoms, or active avoidance of treatment due to positive symptoms such as delusions or imperative voices. To enable stable treatment compliance in patients suffering from schizophrenia, a confidential and empathetic attitude of the people involved is an important prerequisite.

Particular Aspects of Treatment

Pharmacotherapy

The introduction of chlorpromazine into clinical practice in 1952 is the hallmark of the pharmacological treatment of schizophrenia (Delay and Deniker, 1952). Chemically, chlorpromazine is a phenothiazine and other substances of this group also possess antipsychotic properties. In the 1950s and 1960s, numerous antipsychotic drugs with different structures (in particular butyrophenones (e.g., haloperidol) and thioxanthenes (e.g., flupentixol)) were developed. Despite this diversity in chemical structure, these first-generation drugs do not differ qualitatively with respect to their profile of beneficial and undesired effects. They target mainly the positive symptoms of schizophrenia mentioned in **Table 2** without preferentially affecting one or the other of these symptoms. Their effectiveness does not depend on the subtype of schizophrenia (see **Table 1**).

The common mode of action of the first-generation antipsychotics is believed to be blockade of the D2 subtype of dopamine receptors (Pickar, 1995). Blockade of these receptors in the mesolimbic dopamine system is thought to cause a reduction in positive symptoms, and blockade in the nigrostriatal dopamine system is believed to be responsible for the typical side effects of these drugs. These are severe disturbances of motor behavior caused by a drug-induced dysfunction of the dopaminergic extrapyramidal system, which plays a pivotal role in the control of movements. **Table 3** summarizes these extrapyramidal syndromes. Those which occur acutely are often very disturbing, but respond fairly well to treatment (e.g., acute dystonia to anticholinergic drugs), or at least cease upon drug discontinuation or dose reduction. Tardive extrapyramidal syndromes, however, are frequent (5–10% on long-term treatment with first-generation antipsychotics), often resistant to treatment approaches, and they usually persist if the antipsychotic drug is stopped. Another severe side effect of unknown cause, which might be related to the extrapyramidal system, is the neuroleptic malignant syndrome (Pelonero et al., 1998; see also Section Emergency Treatment). Extrapyramidal side effects are common to all first-generation drugs, whereas other, less specific side effects (e.g., sedation, weight gain, postural hypotension) occur with some but not all substances (see Psychopharmacotherapy: Side Effects).

Due to the central role attributed to D2 dopamine receptor blockade, it has been thought for a long time that antipsychotic effectiveness and extrapyramidal syndromes are inevitably linked to each other. However, in the late 1960s it turned out that the dibenzodiazepine clozapine is a potent antipsychotic drug that almost never induces extrapyramidal symptoms and is effective in a proportion of otherwise treatment-resistant patients (Angst et al., 1971). Moreover, it was shown that clozapine not only improves positive but to some extent also negative symptoms. Therefore, the introduction of clozapine into clinical practice was the first qualitative advance after the discovery of chlorpromazine, and it is justified to call this substance a second-generation antipsychotic drug. Unfortunately it turned out quickly that clozapine has a very particular and important drawback: it induces life-threatening agranulocytosis in about 1% of patients treated (Baldessarini and Frankenburg, 1991). Therefore, the use of this drug is only possible when white blood cell counts are monitored in short intervals.

It is still not known why clozapine is a potent antipsychotic drug, but lacks extrapyramidal side effects. Among the possible reasons are that clozapine affects mainly the mesolimbic

Table 3 Extrapyramidal syndromes induced by first-generation antipsychotic drugs

Acute (within days)	*(Late or tardive (within months to years))*
Drug-induced Parkinsonism (*bradykinesia, increased muscular tone, tremor*)	Tardive dyskinesia or dystonia (*irregular choreiform, or dystonic movements in any voluntary muscle group*)
Dystonia (*sudden-onset, sustained muscular contractions preferably in the cephalic musculature*)	Tardive tics (*repetitive, short-lasting, stereotyped movements or other kind of behavior (e.g., vocalization)*)
Akathisia (*internal restlessness and urge to move, often coupled with pacing behavior*)	Tardive myoclonus (*brief asynchronous movements which are not stereotyped*)

dopamine system, that it blocks D1 receptors to the same extent as D2 receptors, that it has a high affinity to D4 receptors, and that it also has high affinity to serotonin receptors. This theoretical framework was the basis for the development of various second-generation antipsychotics (see Table 4). Most of them have high affinities for serotonin receptors, although only one substance (olanzapine) is similar to clozapine in the equivalent binding to D1 and D2 receptors. So far there is no indication that any of these newer drugs carries a substantial risk of agranulocytosis, the most dangerous side effect of clozapine. Moreover, these substances have shown to be effective when compared to first-generation antipsychotic drugs and indeed to induce fewer extrapyramidal side effects. For two of them (olanzapine and risperidone) there are data suggesting that they also might ameliorate negative symptoms. However, it still remains to be seen how the effectiveness of these newer drugs compares to clozapine.

Treatment with antipsychotic drugs in schizophrenic patients is usually a long-term treatment continuing for many years. Intermittently, patients may need additional other psychotropic medications. Most frequently anxiolytics, hypnotics, and antidepressants are administered. The recognition and treatment of intervening depressive episodes is particularly important because depressive and negative symptoms are sometimes difficult to differentiate, but need different treatment. When administering antidepressant drugs to schizophrenic patients, one should be aware that during treatment with antidepressants positive symptoms sometimes exacerbate.

Psychosocial Treatment

It is now generally accepted that psychosocial treatment of patients with schizophrenia is not an alternative to pharmacological treatment, but rather an important complementary approach (Bustillo et al., 2000). Psychosocial measures yield little benefit for positive symptoms; in contrast, intensive psychodynamic psychotherapy might induce exacerbations. The most important and successful interventions are psychoeducative teaching and training in social skills and problem solving. Although it is still debated whether these treatments are directly effective against negative symptoms, there is no doubt that they considerably improve coping with these symptoms.

The major goal of educational approaches is to increase the knowledge about and the insight into the disease process and, as a consequence, to improve treatment compliance. Educational programs are focused on knowledge about the disease process and it's course, the mode of action and side effects of medication, early signs of exacerbation such as restlessness and insomnia, and detailed information about the various community based or hospital facilities available. These programs are particularly effective when important family members are educated as well. Moreover, approaches to improve the communication styles within the patient's network of social relationships are often useful, although the concept that particular forms of communication ('high expressed emotions') play a causative role in schizophrenia has been seriously challenged.

Schizophrenic patients' social skills are often poor. This is one major reason for the often dramatically reduced amount of social contacts. Training of social skills in patients suffering from schizophrenia is performed in a group setting. Such groups are focused on the repetitive training of behavior in various social situations of importance for everyday life. In addition, some rather basic teaching of the theoretical background of successful social interaction might be included.

Impaired problem solving in schizophrenic patients is due to a combination of disturbances in divided attention, planning, and motivation. Problem solving training includes the analysis of problems relevant to daily life and, particularly, dividing a problem into subproblems that can be successively solved. Similar to the training of social skills, the steps of the solution are practiced repeatedly.

In recent years, more complex psychotherapeutic approaches have been developed, combining cognitive, behavioral, or psychodynamic approaches, which, however, are suitable for the minority of patients only.

In particular for chronic patients who in earlier times often were hospitalized for decades, providing supervised residential living arrangements has proven to be of considerable benefit because in this setting the degree of self-sustainment can be maximized in parallel with the permanent provision of professional help.

Emergency Treatment

Schizophrenia is not only a debilitating but also a life-threatening disorder. If severe positive symptoms are present, such as verbal imperative hallucinations, delusions of persecution, or severe formal thought disturbances, the patient's life is threatened by a misinterpretation of his or her environment

Table 4 Relative receptor affinities of selected newer antipsychotic compounds compared to the first-generation drug haloperidol

	(Dopamine)		*(Serotonin)*		*(Noradrenaline)*		*Histamine*	*Acetylcholine*

(e.g., of dangerous objects or situations) and by suicidal intentions. Suicidality can also emerge when negative symptoms are prominent. Acute suicidality and an acute confusional psychotic state both necessitate immediate treatment, including the administration of anxiolytics, antipsychotics, or both, preferably in a hospital setting. Although every effort should be undertaken to get the informed consent of the patient, it is often necessary to initiate treatment against his or her explicit will. This has to be done in accordance with the legal regulations in the respective country.

Less frequently occurring life-threatening situations in patients suffering from schizophrenia are febrile catatonia and the neuroleptic malignant syndrome, a rare side effect of antipsychotic drugs (Pelonero et al., 1998). Both conditions show similarities, including fever, disturbances of motor behavior, and reduced responsiveness to external stimuli. The differential diagnosis is difficult, but very important because in febrile catatonia treatment with antipsychotic drugs is necessary, whereas such treatment has to be immediately stopped when a neuroleptic malignant syndrome is suspected. In both of these conditions admission to an intensive care unit is necessary.

Future Perspectives on the Treatment of Schizophrenia

Despite the rapid development of the knowledge about human genetics, it is unlikely that we will see a major advance in our understanding of the genetic causes of schizophrenia in the near future. The reason is that the available epidemiological data render a major contribution of single genes quite unlikely and suggest that multiple genes contribute to the susceptibility to schizophrenia. However, it is likely that genetic investigations will improve the management of schizophrenia by enabling prediction of the treatment response to antipsychotic drugs. Very recently, for example, it has been shown that a combination of six polymorphisms in neurotransmitter-receptor-related genes enable a significant prediction of the treatment response to clozapine (Arranz et al., 2000). Although these preliminary studies must be replicated and extended to other drugs, it is probable that this approach will significantly enhance the success of drug treatment in schizophrenia. It is also likely that the near future will bring new drugs which are the result of a 'fine-tuning' of the chemical structure and the binding profile to dopamine and serotonin receptors of those substances which are presently available. Another approach which is currently being pursued is to target glutamate receptors, although first clinical trials are only in part encouraging (Farber et al., 1999). Based on a theory implicating the immune system in the pathophysiology of schizophrenia, studies are being started that use immunomodulation as a treatment. This is an interesting and promising approach, which also might help to understand the mode of action of presently available antipsychotic drugs because some of them influence the production of cytokines which are important immune mediators (Pollmächer et al., 2000). Another approach based on pathophysiological theories is to target phospholipids. These are an important cell-membrane component and there is some evidence suggesting that either their uptake is deficient or that they are excessively broken down in schizophrenic patients (Horrobin, 1999).

Schizophrenia: Metabolic Consequences

Antonio Ventriglio and Antonello Bellomo, University of Foggia, Foggia, Italy
Dinesh Bhugra, Institute of Psychiatry, King's College, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

People affected by schizophrenia and other severe mental illnesses show a reduced expectancy of life as compared with the general population because of a high rate of comorbidities (obesity, diabetes, hypertension, dyslipidemias, metabolic syndrome) and unhealthy lifestyles. In fact, the cardiometabolic risk is considered to be higher for people affected by schizophrenia with a two- to threefold increased risk of death mostly from cardiovascular and metabolic disease. Antipsychotic agents are an effective and necessary component of the management of such major severe mental illness. Although there may be an independent link between schizophrenia and metabolic conditions, there is a considerable literature regarding the metabolic adverse effects of antipsychotic agents, particularly for the second-generation antipsychotics. Over recent years, international organizations have developed screening and monitoring guidelines in order to reduce modifiable risk factors, comorbidity, and mortality rates among patients affected by schizophrenia and improve the outcome of illness, including patients' functioning and quality of life.

Introduction

People affected by schizophrenia and other severe mental illness show a reduced expectancy of life as compared with the general population because of a high rate of comorbidities and unhealthy lifestyles (Saha et al., 2007; Fleischacker et al., 2008).

In fact, they report a two- to threefold increased risk of death mostly from cardiovascular and metabolic disease (Saha et al., 2007; Fleischacker, 2008). In 2004 the American Diabetes Association (ADA, www.diabetes.org) promoted an initiative regarding the cardiometabolic risk (CMR) in the general population and identified some risk factors considered to be modifiable (overweight/obesity, high blood glucose, hypertension, abnormal lipid metabolism, physical inactivity, smoking) or nonmodifiable (age, race and ethnicity, gender, family history). The CMR is considered to be increased for people affected by schizophrenia and major mental illness since prevalence and relative risk of modifiable factors are higher in the psychiatric population as compared with the general one (Correll, 2007). Also, many authors (Fleischhacker et al., 2008; Newcomer, 2005; Cradock-O′ Leary et al., 2002; Druss et al., 2001) describe that schizophrenia patients may have poorer access to health care and an unhealthy lifestyle (poor diet and physical exercise).

In the last decades, many authors have demonstrated that antipsychotic agents (APs) may have a great impact on the modifiable risk factors leading to weight gain and significant metabolic changes among patients treated (Nasrallah, 2008; Newcomer, 2007; Papanastasiou, 2013). Also, metabolic syndrome that is a constellation of clinical conditions, recognized as independent risk factors for cardiovascular disease (including abdominal obesity, insulin resistance, dyslipidemias, hypertension), is highly prevalent in individuals with schizophrenia and conveys significant cardiovascular risk and mortality (Papanastasiou, 2013).

Figure 1 summarizes all factors involved in the increased risk for cardiometabolic diseases among schizophrenia patients.

Mortality in Schizophrenia

Correll in 2007 estimated that the prevalence of CMR modifiable factors and relative risk (RR) are higher among patients affected by schizophrenia as compared with the general population. In fact those patients are more likely to be overweight/obese (45–55%, RR: 1.5–2), smokers (50–80%, RR: 2–3), to have diabetes (10–15%, RR: 2), hypertension (19–58%, RR: 2–3), dyslipidemias (25–69%, RR $\leq$ 5), and metabolic syndrome (37–63%, RR: 2–3). The median

Figure 1 Cardiometabolic risk (CMR) among patients affected by schizophrenia.

all-causes standardized mortality ratio (SMR) for people affected by schizophrenia was 1.84 in the 1970s, 2.98 in the 1980s, and 3.20 in the 1990s, with an increasing mortality over time (De Hert et al., 2009a). In particular, cardiovascular mortality in schizophrenia increased in 1976–95 with the greatest increase in SMRs in men from 1991 to 1995 (Osby et al., 2000). Moreover, medical comorbidities, in particular cardiovascular disease, in patients with schizophrenia may lead to a 20% shorter lifespan (10–15 years) (Harris and Barraclough, 1998; McLean et al., 2014; Castillo Sánchez et al., 2014). In fact, it has been widely described that schizophrenia is associated with premature mortality and a high rate of sudden, unexpected deaths mostly caused by structural cardiovascular, respiratory, and neurological abnormalities, with most cases due to acute myocardial infarction (Ifteni et al., 2014). In conclusion, early recognition and treatment of cardiovascular and metabolic conditions must become a clinical priority for all adults with schizophrenia as the standard risk assessment for such comorbidities underestimates the risk of death in schizophrenia (McLean et al., 2014; Ifteni et al., 2014).

Vulnerability

The link between metabolic abnormalities and schizophrenia has been described before the era of modern antipsychotic drugs. Genetic links between diabetes and schizophrenia have been recognized by Sir Henry Maudsley in his 1897 text, *The Pathology of Mind*, who noted: "Diabetes often shows itself in families in which insanity prevails." Also, weight gain and abnormal eating behaviors were commented by Kraepelin and Bleuler in the beginning of 1900.

Evidence from latest decades confirmed that there may be a link between major mental illness and metabolic conditions without any influence by APs. In fact, metabolic disturbances have been found in drug-naïve patients with first-episode illness and may be an inherent part of the illness.

First-episode, drug-naïve patients with schizophrenia have impaired fasting glucose tolerance, are more insulin resistant, and have higher levels of glucose, insulin, and cortisol than healthy comparison subjects (Ryan et al., 2003; Thakore, 2004). These patients have higher than expected rates of visceral obesity which may be related to a subtle disturbance of the hypothalamic–pituitary–adrenal axis (Thakore, 2004). It has been recently described that molecular abnormalities in metabolic, hormonal, and immune pathways are present in peripheral body fluids of schizophrenia patients. These findings suggest the presence of a molecular endophenotype involving disruption of insulin and growth factor signaling pathways as an increased risk factor for schizophrenia (van Beveren et al., 2014). In addition, drug-naïve, first-episode schizophrenia patients, even if with normal weight, present an upregulated inflammatory status (increased levels of IL-1β, IL-6, and TNF-α) and higher adiponectin levels that may play a proinflammatory role leading to later metabolic abnormalities in this patient population (Song et al., 2013).

Mitchell et al., in 2013, described that metabolic factors (including weight, triglycerides, impaired fasting glucose, cholesterol levels, diabetes, smoking) are lower among patients at first episode of psychosis or unmedicated patients as compared with treated schizophrenia patients, but factors are altered in such early-stage patients and metabolic syndrome may be present in the unmedicated group more than in the first-episode one.

Although the cardiovascular risk is not significantly higher at this stage of illness, the first-episode patients should be screened for the primary prevention of cardiovascular morbidity and mortality (Phutane et al., 2011).

Antipsychotic Agents

Psychopharmacological treatment of schizophrenia is an effective and necessary component for the management of such severe major mental disorder. It has been clearly established that unmedicated patients report much higher mortality and suicide rates, more hospitalizations, and worst outcomes of illness with greater cognitive and functional impairment (De Hert et al., 2009a; Tiihonen et al., 2006).

However, there is a considerable literature regarding the metabolic adverse effects of APs. Growing evidence demonstrates that newer agents, second-generation antipsychotics (SGAs), induce more weight gain and metabolic abnormalities as compared with first-generation antipsychotics (FGAs) (De Hert et al., 2009a; Nasrallah, 2008; Newcomer, 2007; Papanastasiou, 2013).

It has been a shift of risk perception for patients and clinicians employing newer agents, i.e., SGAs, with a major concern regarding metabolic side effects more than extrapyramidal symptoms and tardive dyskinesia. In fact, SGAs are responsible for new cases of diabetes. Although diabetes is considered to be related to other metabolic dysfunctions (hypertriglyceridemia, insulin resistance, and weight gain) observed during the treatment with low-potency FGAs, many types of evidence show that there may be specific diabetogenic actions of some SGAs, in particular for clozapine and olanzapine (Reynolds and Kirk, 2010; Stahl, 2013). The diabetogenic mechanism may involve a muscarinic M3-receptor antagonism, which is remarkable for olanzapine and clozapine. M3 receptors are localized on beta-cells of the pancreas and regulate the insulin release and glucose level homeostasis. M3-receptor blockage might alter glucose metabolism with clinical conditions of diabetes, diabetic ketoacidosis, and hyperosmolar syndrome, all observed in patients treated with olanzapine and clozapine (Reynolds and Kirk, 2010; Stahl, 2013). Weight gain and dyslipidemia (hypertriglyceridemia) are triggering factors for diabetes and are frequently induced by antipsychotics like olanzapine and clozapine whereas aripiprazole and ziprasidone show safer tolerability profiles to be considered in case of switching from other antipsychotics for metabolic side effects (Reynolds and Kirk, 2010; Stahl, 2013). Weight gain might be induced by 5HT2C- and H1-receptor affinity of newer antipsychotics; in particular H1-receptors are localized in the hypothalamus (hunger and satiety centers) and may be involved in inducing hyperphagia. Chlorpromazine, as an FGA, is also associated with weight gain for its high H1-receptor affinity (Reynolds and Kirk, 2010; Stahl, 2013). Other receptor mechanisms may have additive or synergistic

effects; dopamine D2 receptor antagonism can enhance 5-HT2C-mediated effects on food intake, as well as influencing lipid and glucose metabolism via disinhibition of prolactin secretion (Reynolds and Kirk, 2010; Stahl, 2013). SGAs might also have effects on the hypothalamic regions involved in control of food intake: olanzapine enhances neuropeptide Y (NPY) expression in the ARC (arcuate nucleus) (Reynolds and Kirk, 2010).

Table 1 shows the atypical SGAs and their tolerability profiles according to the literature evidence (Leucht et al., 2009a; American Diabetes Association/American Psychiatric Association, 2004; Tschoner et al., 2007; Cohn and Sernyak, 2006; De Hert et al., 2006; De Nayer et al., 2005).

Weight Gain

Weight gain during the acute and maintenance treatment of schizophrenia involves 15–72% of patients (De Hert, 2009). A *metaanalysis* of clinical trials showed significant weight gain with a 10-week antipsychotic treatment ranging as: clozapine (+4.45 kg) > olanzapine (+4.15 kg) > quetiapine and risperidone (+2.1 kg) > aripiprazole and ziprasidone (<1 kg) (Allison et al., 1999; De Hert et al., 2009). This hierarchy of induced weight gain was confirmed by following studies and *metaanalyses* including Clinical Antipsychotic Trials of Intervention Effectiveness (CATIE) and European First Episode Schizophrenia Trial (EUFEST) Studies (De Hert et al., 2009a; Daumit et al., 2008; Leucht et al., 2009b; Goff et al., 2005; Lieberman et al., 2005).

There are some demographic and clinical features associated with a greater propensity for weight gain: younger age, lower initial BMI, personal and family history of obesity, nonwhite ethnic background, tendency to overeat in times of stress, cannabis use, and first-episode psychosis (De Hert et al., 2009a). A comprehensive literature review, however, did not find evidence for a dose–response at the doses used to treat psychotic illnesses for most antipsychotics, except clozapine and olanzapine (Simon et al., 2009).

Although there are significant findings in many other genes involved in the antipsychotic-induced weight gain, the most consistently replicated findings are in the melanocortin 4 receptor (MC4R), the serotonin 2C receptor (HTR2C), the leptin, the neuropeptide Y (NPY) and the cannabinoid receptor 1 (CNR1) genes (Shams and Müller, 2014).

Diabetes

There is a higher risk of developing diabetes mellitus type 2 for people receiving antipsychotic medications. The sources of information range from case histories, through pharmacoepidemiological studies to randomized controlled studies (De Hert et al., 2009a).

Causality between antipsychotic use and the onset of diabetes can be difficult. People with schizophrenia show increased risk for diabetes independent of drug therapy.

In fact, approximately 15% of people with schizophrenia develop diabetes with a prevalence that is approximately two times greater than the general population (Bushe and Holt, 2004). In 2008 schizophrenia was recognized by the Canadian Diabetes Association (CDA) as an independent risk factor for diabetes. The CDA also lists SGAs as a risk factor for diabetes.

In contrast to some studied antipsychotics, clozapine and olanzapine are associated with a concentration-dependent increase in circulating insulin levels thought to be secondary to a direct stimulating effect of these agents on pancreatic insulin secretion (Melkersson et al., 2004). In the CATIE study, there was a significantly greater increase in HbA1c with olanzapine (0.4%) > quetiapine (0.04%) > risperidone (0.07%) > perphenazine (0.09%) > ziprasidone (0.11%) (Lieberman et al., 2005).

A baseline assessment of glucose regulation is important to screen new cases of diabetes due to the antipsychotic treatment. Clinicians managing patients treated in the long term need to make efforts to prevent diabetes and respond to it early when it does occur.

Dyslipidemias

Risk factors for coronary artery disease include increased low-density lipoprotein cholesterol (LDL-C) and/or decreased high-density lipoprotein cholesterol (HDL-C).

Many studies show that the use of antipsychotics is associated with an increase of LDL-C and a decrease of HDL-C (Daumit et al., 2008; Goff et al., 2005).

It has been indicated that the effect on total and LDL cholesterol differs between antipsychotics: drugs associated with the most weight gain, such as clozapine and olanzapine, are associated with the largest increase in serum LDL and triglycerides

Table 1 Side effects of second-generation antipsychotics (SGAs)

	Weight gain	*Dyslipidemia*	*Diabetes*	*EPS*	*Prolactin increase*	*Sedation*	*QT-interval prolongation*
Amisulpride	+	–	+	+	+++	–	–
Aripiprazole	–	–	–	+/–	–	+	–
Asenapine	+/–	+/–	–	–	–	++	–
Clozapine	+++	++	+++	–	–	+++	+
Olanzapine	+++	++	+++	–	–	+++	–
Quetiapine	++	+	++	–	–	++	–
Risperidone	++	+/–	++	+	+++	+	++
Ziprasidone	+/–	–	–	–	+	–	++

+++ = high incidence, ++ = moderate incidence, + = low incidence, – = very low incidence, EPS: extrapyramidal symptoms.
Modified by Leucht, S., Komossa, K., Rummel-Kluge, C., Corves, C., Hunger, H., Schmid, F., Asenjo Lobos, C., Schwarz, S., Davis, J.M., 2009a. A *metaanalysis* of head-to-head comparisons of second-generation antipsychotics in the treatment of schizophrenia. American Journal of Psychiatry 166 (2), 152–163.

(Daumit et al., 2008; Goff et al., 2005). The most marked increase is observed in the early phase of treatment when weight gain occurs most rapidly (Daumit et al., 2008; Goff et al., 2005). Most studies suggest lipid measurements after short periods of treatment (2–3 months) and there is a need to assess what the longer-term effects on triglyceride concentrations are once weight has stabilized (De Hert et al., 2009a). Lipid concentration may decrease rapidly after a psychoeducational and monitoring program (Ventriglio et al., 2014).

Blood Pressure

Increases in blood pressure may occur sporadically, mostly involving clozapine (Gardner and Theean, 2011). Reduction of blood pressure with associated symptoms of feeling weak is a common occurrence with many antipsychotics. Syncopal episodes related to orthostasis may happen, mostly due to low-potency FGAs (α1-adrenergic and calcium blockade are generally thought to account for this adverse effect). Posture-related drops in blood pressure are especially common with FGAs. A slower dosage titration was recommended when it was observed. With most drugs, tolerance develops with continued use, and the effects recede (Gardner and Theean, 2011).

Metabolic Syndrome

The metabolic syndrome (MetS; also called syndrome X or Reaven's syndrome) is a constellation of different conditions, including abdominal obesity, insulin resistance, dyslipidemia, and elevated blood pressure. All components of the MetS have been recognized as independent risk factors for cardiovascular disease and are associated with other conditions such as the prothrombotic state, the proinflammatory state, nonalcoholic fatty liver disease, and reproductive disorders (Papanastasiou, 2013).

Many definitions have been given to MetS: World Health Organization (WHO) in 1985, European Group for the Study of Insulin Resistance in 1999, National Cholesterol Education Program's Adult Treatment Panel III (NCEP-ATP III) in 2001 (modified in 2003), American Association of Clinical Endocrinologists in 2003, and finally by the International Diabetes Federation (IDF) in 2006 (Papanastasiou, 2013).

MetS may be diagnosed if three out of the following five conditions are present in the same patient:

1. Elevated waist circumference, M > 102 cm F > 88 cm (IDF: M $\geq$ 94 cm F $\geq$ 80 cm).
2. Elevated triglycerides ($\geq$150 mg dl^{-1}) or drug treatment for dyslipidemia.
3. Reduced high-density lipoprotein (HDL) (<40 mg dl^{-1}) or drug treatment for hypercholesterolemia.
4. Elevated blood pressure (systolic $\geq$130 mmHg, diastolic $\geq$85 mmHg) or a history of hypertension or drug treatment for hypertension.
5. Elevated fasting glucose ($\geq$100 mg dl^{-1}) or drug treatment for hyperglycemia.

In a large review of literature Papanastasiou (2013) described that the prevalence rates may vary largely across studies (reflecting the groups of patients studied that may be different for age, sex, ethnicity, medication status, smoking, duration of illness, and outcomes). The lowest prevalence rate reported was 3.9%, and the highest prevalence rate reported was 68%, derived from patients treated with FGAs and/or SGAs. MetS shows a peak of prevalence in the fourth/fifth decade of life among patients studied. For patients treated with antipsychotics, clozapine and olanzapine appeared to be related to higher MetS rates than other APs. Also, the reviews show an increase from 24.7% to 49.6% in the comparison between previously unmedicated and currently treated patients. Patients treated with SGAs showed higher rates of MetS as compared with those treated with FGAs (27.8% versus 9.8%) (De Hert et al., 2009b; Papanastasiou, 2013).

Recently it has been described that MetS might aggravate injury of cognitive function in chronic schizophrenia, especially in immediate memory, delayed memory, and attention (Li et al., 2014).

Prolactin Levels

Antipsychotic-induced hyperprolactinemia results from dopaminergic blockade in the tuberoinfundibular dopaminergic system of the hypothalamus. The magnitude of hyperprolactinemia correlates strongly with dopamine D2 receptor blockade potency. Prolactin level may be associated with clinical signs and consequences: galactorrhea, gynecomastia, oligomenorrhea, amenorrhea, galactorrhea, reduced libido, dyspareunia, vaginal dryness for women; gynecomastia, reduced libido, erectile dysfunction, ejaculatory dysfunction for men (Halbreich et al., 2003; Gardner and Theean, 2011). Osteoporosis, hypogonadism, and breast cancer have been associated with prolactinomas, in which prolactin levels can exceed 5000 ng ml^{-1} (Halbreich et al., 2003; Gardner and Theean, 2011).

Hyperprolactinemia occurs more frequently in females than males, despite lower doses used in women. Return to normal prolactin levels occurs rapidly upon discontinuation of treatment (Halbreich et al., 2003; Gardner and Theean, 2011).

According to literature evidence, antipsychotics are associated with increase of prolactin ranging as: risperidone = paliperidone = amisulpride = haloperidol (74–91%)> olanzapine (2–20%) > quetiapine (no significant increase) > aripiprazole = ziprasidone (no significant increase) (Halbreich et al., 2003; Gardner and Theean, 2011).

Prolactin should be measured at baseline and over the follow-up period (monitoring hyperprolactinemia-related signs and symptoms). Prolactin levels range: nonpregnant women: 0–20 ng ml^{-1} (0–424 mIU l^{-1}); pregnant women: $\leq$200 ng ml^{-1} ($\leq$4240 mIU l^{-1}); men: 0–15 ng ml^{-1} (0–318 mIU l^{-1}) (Kratz et al., 2004).

When prolactin levels are high but lower than 150 ng ml^{-1}, clinicians may consider a switch from the current antipsychotic to another, which is not associated with prolactin increase or, taking into account the risk of psychotic rebounds, may introduce a dopamine agonist like cabergoline, bromocriptine, or pergolide. If prolactin levels are higher than 150 ng ml^{-1}, an endocrinology consult is needed and the application of nuclear magnetic resonance imaging to exclude prolactin-producing pituitary and juxtasellar adenomas is required (De Hert et al., 2014).

QT-Interval Prolongation

Recently, many studies have been reporting data on QT prolongation during the antipsychotic treatment.

QT interval is a measure of the time between the start of the Q wave and the end of the T wave in the heart's electrical cycle. In general, the QT interval represents electrical depolarization (Na^+ and Ca^{2+} intake in the cells) and repolarization (K^+ output) of the ventricles.

QT is corrected for heart rate (QTc) derived from the heart rate (HR) as 60 beats per minute according to Bazett's formula.

Although QT may be variable depending on age, sex, and circadian rhythms, a lengthened QT interval is a marker for the potential of ventricular tachyarrhythmias like *torsades de pointes* and a risk factor for sudden death.

A QTc value above 500 ms or an increase of 60 ms (20% from baseline) is strongly associated with arrhythmias and *torsade de pointes* (TdP) (**Table 2**).

APs may prolong QTc interval depending on their binding potency to IKr channels of ventricle repolarization (hERG channels).

SGAs mostly involved with QTc prolongation are ziprasidone, risperidone, paliperidone, clozapine, and quetiapine. Aripiprazole, olanzapine, and asenapine are associated with lower variations in QTc interval (Hasnain and Vieweg, 2014; Gardner and Theean, 2011).

FGAs are responsible for higher QTc prolongations, in particular haloperidol. Thioridazine and sertindole have been withdrawn worldwide since they may lead to arrhythmias and sudden death.

Antipsychotics should be prescribed with caution for patients affected by cardiovascular diseases (congenital long QT syndrome, myocardial infarction, cardiac failure, arrhythmias) or other risky conditions (previous TdP or hypokalemia) (Hasnain and Vieweg, 2014; Gardner and Theean, 2011).

Finally, it is of interest that myocarditis may occur during the treatment with clozapine, in particular in the first 2 months of it (85% of cases). Also, patients treated with chlorpromazine or fluphenazine may present with myocarditis. If clinical signs of myocarditis are suspected (e.g., tachycardia), the drug should be stopped (Gardner and Theean, 2011).

Screening and Monitoring for Metabolic Consequences

Over recent years, national and international groups have developed screening and monitoring guidelines. The aim of such procedures is to reduce modifiable factors associated with the risk of cardiometabolic conditions among patients affected by schizophrenia (De Hert et al., 2009a). We will consider guidelines from the European Psychiatric Association (EPA), supported by the European Association for the Study of Diabetes (EASD) and the European Society of Cardiology (ESC), also known as EPA/EASD/ESC Position Statement (De Hert et al., 2009a).

These recommendations are poorly employed in the clinical settings even if, when applied, they seem to improve the metabolic outcome of schizophrenia patients (De Hert et al., 2009a; De Hert et al., 2011; Ventriglio et al., 2014).

The baseline medical history and examination should include (De Hert et al., 2009a) history of previous cardiovascular diseases, diabetes, or other related disease; family history of premature CVD, diabetes, or other related disease; smoking habit, food selection, physical activity; weight and height in order to calculate body mass index (BMI) and waist circumference; fasting blood glucose; fasting blood lipids: total cholesterol, triglycerides, LDL-C (by calculation), and HDL-C; blood pressure (measured twice and average taken), heart rate, heart and lung auscultation, foot pulses; ECG.

If metabolic parameters are in normal ranges in patients on antipsychotic treatment for more than 12 months, clinicians have to repeat previous factors annually. If values are in normal ranges at baseline in drug-naïve patients, monitoring has to be repeated at week 6, week 12, and annually (paying particular attention to weight gain within the 6th week of treatment) (De Hert et al., 2009a).

In the presence of one or more risk factors, the antipsychotic treatment has to be selected carefully, by a psychiatric and metabolic prospective. Treatment may be required to reduce the cardiovascular risk. Clinicians have to involve general practitioners in order to collaborate with them in managing the risk factors: BMI should be ≤ 25 kg m^{-2}, waist circumference <102 cm (men)/<88 cm (women), blood pressure $\leq$140/90 mmHg – triglycerides <190 mg dL^{-1} – LDL <115 mg dL^{-1} in nondiabetic patients, glycosylated hemoglobin <7% – blood pressure $\leq$130/80 mmHg – triglycerides <175 mg dL^{-1} – LDL <100 mg dL^{-1} in diabetic patients. Statins treatment is encouraged to reach the recommended values of serum lipids (De Hert et al., 2009a). Diabetic patients should repeat glycosylated hemoglobin three-monthly, microalbuminuria, renal

Table 2 QTc-interval values

QTc (ms)	*Males*	*Females*
Normal	<430	<450
Borderline	431–450	451–470
Prolonged	>450	>470

Table 3 Monitoring and screening flow-chart for metabolic consequences (according to EPA/EASD/ESC Position Statement, De Hert et al., 2009a)

Note: Diabetic patients should repeat glycosylated hemoglobin three-monthly, microalbuminuria, renal functioning, ophthalmological and feet examination yearly.

functioning, ophthalmological and feet examination yearly (De Hert et al., 2009a; **Table 3**).

Conclusion

Metabolic consequences of schizophrenia and antipsychotic treatments may increase the risk of mortality among patients affected. In fact, they show higher levels of cardiometabolic comorbidities as compared with the general population and a two- to threefold increased risk of death. Screening and monitoring recommendations from international organizations aim to reduce the comorbidity and mortality rates among patients affected by schizophrenia and might improve the outcome of illness, including patients' functioning and quality of life.

Abstract

Carl Schmitt (1888–1985) was a conservative German public lawyer and political theorist. Schmitt is best known for his trenchant critique of liberal constitutionalism, parliamentary democracy, and legal cosmopolitanism. His contributions to debate on these issues continue to attract scholarly attention today, but they are considered to be highly controversial, due to Schmitt's association with National Socialism. This article presents an overview of the key themes and arguments in Schmitt's major writings, and it offers an assessment of Schmitt's relevance for contemporary political, legal, and constitutional theory.

Biographical Sketch

Schmitt published his first academic works in the field of legal theory in the last years of the Wilhelmine Empire (see for Schmitt's biography: Bendersky, 1983; Balakrishnan, 2000; Mehring, 2009). The most productive period of Schmitt's career, however, was the era of the Weimar Republic (1919–33), which saw the publication of most of Schmitt's major political-theoretical works. In these works, Schmitt often presented himself as a defender of the Weimar Constitution, though on the basis of a rather authoritarian and highly contestable interpretation of that constitution that was rejected by the majority of German public lawyers at the time. In particular, Schmitt championed the claim that the popularly elected president of the Weimar Republic possessed an all but unlimited power of dictatorship, under article 48 of the Weimar Constitution, which would allow him to act as a 'guardian of the constitution' and to legislate and govern, in a situation of constitutional crisis, without any parliamentary support (Dyzenhaus, 1997: 70–85; Kennedy, 2004: 154–178).

While Schmitt seems to have been opposed to the prospect of a National Socialist government before 1933, he quickly sided with the Nazis after Hitler's accession to power and came to be perceived as the 'Crown Jurist' of Nazi Germany (Mehring, 2009: 304–436). While some scholars have argued that Schmitt's willingness to support the new regime was born of his ambition and opportunism, and thus did not indicate an ideological affinity to Nazism (Bendersky, 1983: 195–242), there can be little doubt that Schmitt held strongly anti-Semitic views and that his constitutional ideas of the Weimar period were open to be adapted to the new system (Dyzenhaus, 1997: 85–101; Scheuerman, 1999). Schmitt's active involvement with the National Socialist system, however, was cut short in 1936, when he was accused by academic competitors with better National Socialist credentials of being a turncoat who had sided with the new government only to advance his career.

During the later years of the Nazi period, Schmitt therefore turned his attention increasingly to questions of international law. While Schmitt did attempt to provide a justification for Nazi Germany's claim to hegemony on the European continent, he also developed a general account of the conditions of a stable international legal order.

After the end of the war, Schmitt was briefly detained and interrogated by the allied powers, who considered the possibility of putting Schmitt to trial in Nuremberg. Though nothing came of these plans, and Schmitt was set free, he was not allowed, due to his involvement with the National Socialist regime, to return to his academic position after 1945 (Mehring, 2009: 438–463). Schmitt, nevertheless, remained a highly influential figure in West Germany's conservative intellectual scene until his death in 1985 (Müller, 2003). He continued to publish occasionally and to informally supervise young academics.

Schmitt on Sovereignty and Dictatorship

In his early *Political Theology* (Schmitt, 2005), Schmitt famously defends the continuing relevance of sovereignty, both to legal theory and to political practice.

Liberal constitutionalism, according to Schmitt, aims to banish sovereign authority from political life, while it declares the concept of sovereignty to be theoretically dispensable. Its goal is to subject all exercises of political power to the rule of law. But in Schmitt's view, liberal constitutionalism overlooks that the applicability of general legal norms that are to control the exercise of political power presupposes a situation of social normality. No law, Schmitt argues, can be applied to a situation of utter chaos or disorder. Rather, such application requires a 'homogeneous medium,' a situation of social normality, so that the application of the norm will lead to predictable results. A state of emergency or of exception, on the other hand, cannot be governed by legal norms, because a legislator cannot foresee what measures may turn out to be necessary to pacify and normalize an abnormal situation of grave crisis (Kahn, 2011; Croce and Salvatore, 2012). Schmitt concludes that a political community, or rather someone who can act on its behalf, must be endowed with the power to completely suspend the application of the law, and then to use dictatorial measures to restore a state of normality. This conclusion underpins Schmitt's famous claim that 'sovereign is he who decides on the exception' (Schmitt, 2005: 5).

Schmitt is not referring here to an established constitutional competence. What he argues, rather, is that sovereign authority is manifested in the successful exercise of the power to take a decision on the exception so as to create the conditions of the applicability of law. Schmitt holds that any legal order, even one where the constitution does not endow anyone with an

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61279-5

authority to declare a total exception, is based on a decision (to suspend the legal order or not to suspend it), and not on a norm. The fact that the constitutional façade of a modern, liberal-democratic political system typically does not show a sovereign authority, Schmitt thinks, is irrelevant to this point. The true sovereign will appear in a situation of crisis.

Schmitt concedes that a defense of sovereignty for the contemporary world cannot return to the age of absolutism, and portray sovereign authority as vested, by divine right, in a particular person or family (Schmitt, 1985: 22–32, 2008a: 101–111). The doctrine of sovereignty must, therefore, be translated into a democratic ideological context. It is hard to see, though, how such a translation would work. In a democratic context, after all, sovereignty ultimately rests with the people. But the people, it seems, will be able to take collective decisions only once constitutional rules have been put in place that allow them to speak with a united voice. The people, it would appear, are not a suitable bearer of Schmittian sovereignty who takes a decision on the exception.

Schmitt attempted to solve this difficulty through his conception of sovereign dictatorship, which he put forward in his seminal study on the history of the institution of dictatorship (Schmitt, 2014; McCormick, 1997: 121–156; Cristi, 1998: 108–125).

Though originally distinct, dictatorship and sovereignty, Schmitt argues, nevertheless, entered into an intimate relationship in the course of the French Revolution. The French Revolutionary governments employed extralegal, dictatorial force not merely – as the Romans had done – to restore the condition of social normality presupposed by an existing constitution, but so as to create a new situation of normality that would allow a new constitution to come into force. However, the French Revolutionary governments did not claim to be the sovereign. Rather, they took themselves to exercise sovereign authority in the name of the people.

Schmitt's systematic claim here is that democratic constituent power, the power of the people to give itself a new constitution, can only be actualized in the form of sovereign dictatorship: The sovereign people by itself, as an unorganized mass, cannot purposefully act outside the law to create a new situation of normality that will allow for the establishment of a new constitution. It needs to be led by a person or group of persons exercising dictatorial power in the name of the people. But this person or group is dependent on the trust of the people, on the people's willingness to be led and to accept the decisions taken and measures implemented as its own. Sovereign authority, then, still exists in a democratic state: it is the power to take the decision on the exception, so as to establish a new constitutional condition, insofar as it is exercised, and successfully, by appeal to the will of the people (Schmitt, 2008a: 109–110, 265–266).

The Concept of the Political and the Critique of Liberalism

Schmitt's conception of democratic sovereignty assumes that a people or political community can exist prior to or outside of an established framework of constitutional rules. Schmitt's famous claim that politics is based on a distinction between friend and enemy (Schmitt, 2007: 26; Kennedy, 2004: 92–118; Slomp, 2009: 21–37) may usefully be understood as an attempt to explicate the way in which a political community can exist outside of any legal or constitutional framework.

Schmitt emphasizes that the distinction between friend and enemy is essentially public, not private. Politics involves social groups that face off as mutual enemies. Two groups are in a situation of mutual enmity, if and only if, there is a possibility of violent conflict between them. The distinction between friend and enemy marks the 'utmost degree of intensity … of an association or dissociation' (Schmitt, 2007: 26). The utmost degree of association, in other words, is the willingness to fight and to die for a group one identifies with, while the ultimate degree of disassociation consists in the readiness to kill others for the reason that they are members of a hostile group. A political community, then, differs from other kinds of community in that it disposes off the life of its members. Hence, wherever people are members of several kinds of community at the same time, political community will remain the decisive community, and it will typically manage to keep all disagreements between its members below the threshold of violent conflict.

Every political community, in Schmitt's view, requires a substantive collective identity. People who unite into political community must agree to rely on some commonality between themselves as the mark of inclusion in (or exclusion from) the community. But Schmitt does not think that there is any particular kind of difference of identity that is necessarily political. Neither does he hold, consequently, that the distinction between friend and enemy must always be based, in whole or in part, on some particular kind of difference. All kinds of differences of identity – be they ethnic, religious, linguistic, economic – can turn into the substance of a political difference if they turn out, in particular historical context, to have the power to sort people into mutually hostile groups (Schmitt, 2007: 25–27). It would therefore be naïve, Schmitt thinks, to hold that the political will disappear once the conflicts arising from a particular difference of identity have been solved or become irrelevant. History suggests, rather, that political conflict will simply latch on to another difference of identity (Schmitt, 2007: 80–96).

Finally, Schmitt argues in the *Concept of the Political* that a group can be said to exist as a political community only as long as it is self-determining (Schmitt, 2007: 45–53). The members of a group that is to qualify as a political community must take the friend–enemy decision that differentiates their community from other polities by themselves and for themselves. If the friend–enemy decision is taken for a group, but not by the group, but rather by some external power, the group no longer exists as a political community. It follows from this that to deny a group the right to draw the friend–enemy distinction as it sees fit, for example by subjecting it to some binding international regime for the solution of conflict, is to deny the political existence of the group. As long as politics as such is considered to be legitimate, Schmitt concludes, any political community must be entitled to reject such an assault on its political existence.

Schmitt's analysis of the political is at least partly descriptive. The claim is that human beings, throughout history, have shown a tendency to form political communities based on a friend–enemy distinction. A group's ability to take that

distinction, Schmitt holds, does not presuppose that the group is already formally organized, that it already possesses a system of explicit constitutional rules for the creation of a common will. A political community, rather, can have a common existence prior to all legal form as long as its members identify with the substance of the group's identity strongly enough to be willing to fight and die for it. As long as a political community in this sense exists, it will be capable to support a sovereign dictatorship exercised in its name (Schmitt, 2008a: 126–135).

Though partly descriptive, Schmitt's conception of politics has clear normative implications. These are made explicit in Schmitt's critique of liberalism.

In Schmitt's view, liberalism's main characteristic is that it attempts to avoid genuinely political decisions (McCormick, 1997; Dyzenhaus, 1997: 58–70). According to liberals, it is not necessary or desirable for individuals to form groups constituted by friend–enemy distinctions. Liberals hold, rather, that all conflicts among human beings can, in principle, be solved through amicable compromise, as well as through the improvement of civilization, technology, and social organization. Consequently, liberalism is unable to provide markers of identity that can become the basis of political community. While liberalism aims to domesticate political power, in the name of individual freedom, it lacks the power to constitute political community (Schmitt, 2007: 69–79, 1985: 33–50).

This problem, Schmitt thinks, manifests itself in the inability of a liberal state to draw a distinction between friend and enemy. A liberal state will tend to recognize as citizens, and to offer legal protection to, all those who live law-abidingly under the rules laid down in some formal constitution. In doing so, however, liberal states are likely to extend membership to individuals who do not truly identify with the political community that underpins the state. Hence, there is a danger that, in a liberal system, the aims of the political nation will come to be frustrated by internal enemies who abuse the protection afforded by constitutional legality. Eventually, Schmitt, fears, the political nation will slowly disappear, as a result of a process of depoliticization encouraged by liberal ideology (Schmitt, 2008b: 65–77).

It is the job of the sovereign dictator, in Schmitt's view, to prevent such political disintegration, by means of a dictatorial suppression or elimination of internal enemies in a state of exception. In thus protecting the substantive homogeneity of the people, the sovereign dictator creates the condition for the legitimate applicability of the law. The application of constitutional law in nonhomogeneous society, Schmitt argues, can only lead to the legalized suppression of one social group by another (Schmitt, 2008b). Liberal protections of individual freedom and of rights of political association are to be welcomed, therefore, only once all citizens subscribe to a homogeneous political identity.

Though Schmitt expresses confidence that the political will not disappear any time soon, he appears to admit that a completely depoliticized global liberal utopia is possible. The claim that liberalism intends a depoliticization of the world, even if true, thus raises the further question as to why one should judge that the realization of a liberal utopia would be undesirable.

Schmitt offers a number of different responses to this challenge. A first answer emphasizes the Hobbesian claim that the authority of a state is dependent on its power to protect citizens. A state that has suffered a subversion of the political, due to the spread of liberal ideology, may turn out to be incapable to mobilize the coercive force that is needed to protect its subjects, either from an indirect rule of pluralist interest groups who have colonized the state or from external enemies seeking to subdue the political community (Schmitt, 2007: 37–45, 51–53). Schmitt also argues, secondly, that a life without politics would be shallow and meaningless. A completely depoliticized world would offer human beings no other identity than that of a producer and/or consumer. In such a world, there would no longer be any values that would license risking one's own life, and thus give a meaning to one's existence that transcends the satisfaction of private desires (Schmitt, 2007: 35, 57–58). Finally, Schmitt intimates that the willingness to distinguish between friend and enemy is a theological duty (Schmitt, 2005; Meier, 1998). Liberalism, in this reading, is to be rejected because it purports to offer a secular redemption from man's fallen and corrupted nature. But such a promise, as well as the attempt to realize it, is to be rejected, Schmitt appears to suggest, as a rebellion against God, since it is God alone, but only at the end of history, who will deliver humanity from political enmity.

At any rate, Schmitt argues that the political is unlikely to disappear as long as there are at least some who are willing to stake their existence on the attachment to a political identity. Wherever there is one political community, it will force other communities to choose a political existence or to accept subjection. To avoid the latter fate, Schmitt warns, Germans must remain willing to live politically. His analysis of the political at times shades over into a plea for living politically. Schmitt is not just a theorist, but also a partisan of the political.

Schmitt's Theory of Democracy and Constitutional Theory

Democracy, literally, is the self-rule of the people. Or as Schmitt prefers to put the point: a democratic political system must be characterized by the fact that the ruling will is identical to the will of the ruled (Schmitt, 1985: 25–30).

In political practice, of course, such democratic identity is merely presumed, for instance, when the decision of a majority (or of a majority of representatives) is regarded as the decision of the people as a whole. One must therefore ask for the conditions under which the identification of the will of the majority with the will of the whole is justified. Schmitt's answer, unsurprisingly, is based on his analysis of the political. Schmitt claims, as we have seen, that every political community is based on a constitutive distinction between friends and enemies. The equality of democratic citizens, he concludes, must not be confused with the general equality of all human beings. It is an expression, rather, of a shared substantive identity (Schmitt, 2008a: 255–267).

A legitimate identification of the will of the majority with the will of all, then, presupposes that all those who participate in a democracy share one and the same substantive identity. It is only under this condition that one can demand of the members of an outvoted minority that they accept the majority's choice as their own. Schmitt goes on to argue that the ideal of democracy

is not as intimately tied to majoritarian decision-taking as we are inclined to believe (Schmitt, 1985: 28–32). Forms of collective decision-taking other than majority voting may well turn out to be expressive of an identity of ruler and ruled. A populist dictatorship claiming to exercise the sovereignty of the people, Schmitt argues, need not be any less democratic than a system of majority rule, if the dictator and his followers indeed share a political identity. A system of majority voting, on the other hand, whether direct or representative, may turn out not to be democratically legitimate if it is not expressive of an underlying identity. In that case, the rule of the majority will degenerate, Schmitt holds, into an illegitimate and potentially oppressive rule of one social faction over another.

Above all, Schmitt is emphatic that democracy must not be identified with parliamentary government (Schmitt, 1985). The principle of legitimacy of parliamentary government, Schmitt believes, is not democracy, i.e., the identity of ruler and ruled, but rather the view that parliamentary deliberation, in front of an interested and educated bourgeois public, is most likely to lead to correct or sound legislative decisions that cater to the common interest. Schmitt is convinced that this assumption does not apply to modern mass-democracies, where parliaments are controlled by tightly organized parties that represent firmly entrenched social interests. Since parliament has become the scene of a pluralist disintegration of the political community, its decisions are not likely to be expressive of a shared interest or political identity of the whole.

The general effect of Schmitt's reflections on democracy is to dissociate the ideal of democracy from the institutional forms – majority rule and parliamentary government – with which it is most commonly associated, and to link it up with exercises of sovereignty in a state of exception. This revisionist understanding democracy informs Schmitt's constitutional theory and his interpretation of the Weimar Constitution (Dyzenhaus, 1997: 38–101; Scheuerman, 1999: 61–84; Kennedy, 2004: 119–153).

Schmitt's *Constitutional Theory* argues that a democratic constitution is not to be regarded as a social contract, but rather as a unilateral determination, on the part of an already existing political community, of the concrete institutional form of its political existence. The constituent power of the people, i.e., its power to choose for itself any constitution it sees fit, is inalienable, since the people, as long as it exists as a political community, always retains the ability to engage in renewed exercises of constitution-making (Schmitt, 2008: 75–77, 125–130, 140–146; Kalyvas, 2008: 79–186).

Of course, it would make little sense to claim that any written constitution is ever a choice of the people down to its last detail. A people, Schmitt thinks, can do no more than to express its preference for a certain basic constitutional structure, which will then have to be filled out and concretized by the sovereign dictator acting in its name. But it would be wrong, Schmitt holds, to think that the particular norms of a written constitution possess the same normative force as the people's original choice for a certain kind of political system. Even where a written constitution that implements the people's choice for a certain kind of political regime does not impose any material limits on the constituted power of constitutional amendment, it would still be unconstitutional, Schmitt argues, to use that power to transform the very identity of the polity. Such an action, even if it was supported by a supermajority of members of parliament, would amount to usurpation, on the part of constituted powers, of the constituent power of the people (Schmitt, 2004: 85–94, 2008: 77–82, 147–158).

Before 1933, Schmitt relied on this argument to oppose a formally legal Nazi seizure of power. However, Schmitt's constitutional theory did not provide a principled defense of the liberal and democratic constitutional system of the Weimar Republic. While Schmitt denied the constitutionality of changing the fundamental nature of the constitution from within, he, nevertheless, endorsed the possibility of fundamental constitutional change through sovereign dictatorship. Hence, his constitutional theory deliberately left open the possibility of a renewed exercise of constituent power that would sweep away the liberal and parliamentary democracy of the Weimar Republic.

The ambiguity of Schmitt's position toward the Weimar Constitution is equally visible in his interpretation of the powers of the president under the Weimar Constitution (Schmitt, 1931, 2014: 180–226). By assimilating the powers of the president under article 48 of the constitution to those of a sovereign dictator, Schmitt defended an unusually extensive interpretation of presidential authority that subjected most constitutional rights to the discretionary interference of the executive headed by the president. At the same time, Schmitt vehemently opposed the establishment of a constitutional court for the protection of the Weimar Constitution. Such a court, Schmitt argued, would have to limit itself to uncontroversial cases or it would have to act as a constitutional legislator that illicitly claims the power to determine the political identity of the people.

Schmitt seems to have hoped, during the terminal crisis of the Weimar Republic, that presidential dictatorship in defense of the existing constitution would be able to recreate a situation of normality that would allow the constitution to come to function properly again (Kennedy, 2004: 154–183). But Schmitt's theory of presidential guardianship of the constitution is at times difficult to distinguish from a call for an authoritarian transformation of the constitution. The project, at any rate, failed when the Nazis managed to take power through the kind of abuse of constitutional procedure, Schmitt had warned against.

It did not take Schmitt very long to throw in his lot with the new regime, and to offer his services as a legal advisor. Schmitt's readiness to support the Nazis has often been explained as the result of mere personal ambition and opportunism. However, Schmitt's constitutional theory clearly did allow for an interpretation of the Nazi *Machtergreifung* as a valid exercise of constituent power. It thus had the potential to portray Hitler's rule as perfectly legitimate. Hence, it seems unnecessary to postulate a deep discontinuity between Schmitt's views before and after 1933 (Dyzenhaus, 1997: 82–101; Scheuerman, 1999: 113–139).

Liberal Cosmopolitanism and the Foundations of International Legal Order

Schmitt's conception of the political implies two conditions of the legitimacy of international order (Hooker, 2009; Slomp,

2009). Every true political community must claim an unrestricted *ius ad bellum* or right to decide whether to go to war to protect what it sees as its vital interests. If a group no longer takes the distinction between friend and enemy by itself – if that distinction is taken for the group, for instance, by a hegemon or an international organization – the group in question no longer exists as a political community. Hence, an international order that acknowledges the legitimacy of politics must recognize the *ius as bellum* of all groups that have successfully constituted themselves as political communities. Second, Schmitt's conception of the political implies that a group can only exist as a political community if there is at least one other political community that is its enemy. Since the friend–enemy distinction must be based on a difference in substantive identity, politics depends on the availability of several identity-defining forms of social and political life. As a result, an international order that makes room for the political must acknowledge that there are several legitimate forms of social and political life.

These two demands may appear to be a recipe for anarchy, as they seem to rule out an international legal order that successfully regulates the use of force between political communities and that imposes minimal human rights standards on the several members of international society. Schmitt's reply to this objection is to argue that attempts to suppress the *ius ad bellum* and to impose standards of moral conformity on the internal governance of members of international society will only lead to greater disorder and violence than we can expect to see in an international order that is built on a recognition of the political.

Schmitt's argument for this claim proceeds by way of historical example (Schmitt, 2003). Traditional European public international law, the *ius publicum Europaeum*, did not distinguish, according to Schmitt, between just and unjust war. Rather, it acknowledged that every European state had the right to decide to go to war on the basis of its own judgment of justice and necessity. In interstatal wars, both parties were by default recognized as legitimate belligerents. This practice, Schmitt argues, had a number of beneficial consequences that restrained the destructive force of war. The refusal to apportion blame for war made it easier for states to make peace. States not directly involved in a conflict, moreover, were free to adopt a posture of neutrality or to side with either belligerent. This freedom allowed states to contain conflicts by balancing or simply by staying out of the fight. Finally, the mutual recognition of legitimate belligerency permitted states to agree, on the level of the *ius in bello*, on stringent constraints on the permissible means of warfare.

This containment of war, Schmitt argues, was contingent on the willingness to bracket the question of whether wars had a just cause or not (Schmitt, 2011: 30–74). If one adopts the view that a war is usually legitimate or just on one side, but illegitimate or unjust on the other, one is forced to conclude, Schmitt argues, that it must be morally wrong to grant the status of legitimate belligerency to both parties. But in that case, it will no longer be possible to hold on to the view that third parties have a right to side with either belligerent or to remain neutral. One will have to hold, rather, that they are obliged to side with the belligerent that fights justly. Moreover, it will become more difficult to make lasting peace after a war if one side is to be punished for having waged an unjust war. Most importantly, the refusal to accept mutually legitimate belligerency will put pressure on the protections afforded by the *ius in bello*. If one party to a violent conflict is perceived to fight unjustly, it will seem legitimate to use more destructive methods against it than would otherwise appear permissible. Any attempt to create an international order based on a 'discriminatory concept of war' that will subject a political community's decision to use force to substantive criteria of legal or moral legitimacy, Schmitt concludes, is only going to undercut the containment of war achieved by the *ius publicum Europaeum*.

In the *Nomos of the Earth* (Schmitt, 2003), Schmitt tried to answer the question how a regime of the containment of war might come to be constructed on a global level. Groups that are related by mutual enmity can come to coexist in a shared framework that limits the destructive consequences of war, Schmitt proposes, if their enmity does not reach the level of absolute enmity. Enmity, in other words, must take a form that does not require the complete destruction of the enemy's political or even physical existence. Absolute enmity can be prevented, Schmitt holds, if friend–enemy distinctions are aligned with territorial boundaries. If the forms of life of two opposing groups are each tied to and expressed in a particular territory, the friend–enemy distinction between them will have become spatialized. As a result, the defense of a group's political existence can take the form of a defense of its own territory. It will not require the group to interfere with the internal organization of some other polity or to eliminate the latter's political existence.

To spatialize the friend–enemy distinction it is necessary, however, that all and only the people who share one and the same political identity live in the same territory. Some political identities resist such a spatialization of the political. A political community, for instance, whose identity is based on the promotion of liberal-humanitarian values that it takes to be universal, is unlikely to accept a reduction of political conflict to territorial conflict. It will want to interfere where another polity's internal order fails to live up to those values. A stable international order that limits the destructive consequences of political conflict will thus remain out of reach, Schmitt believes, as long as the world's foremost powers are committed to ideologies that imply a rejection of the spatialization of conflict. The way forward to the construction of a durable international order, Schmitt concludes, must consist in division of the globe into several hegemonial spheres that are characterized by internal ideological homogeneity and that recognize each other as mutually legitimate belligerents despite their ideological differences (Schmitt, 2011: 75–124).

Schmitt's theory of the basis of international order is closely related to his account of the conditions under which a domestic constitution can function well. The spatialization of conflict requires political communities capable of enforcing internal political homogeneity. Political communities are likely to be unable to enforce internal homogeneity, however, if they have to live in an international environment that lacks a clear spatial order, because it is controlled by powers committed to universalistic ideologies. Legitimate domestic and legitimate international order, then, are two sides of the same coin for Schmitt (Vinx, 2013). Both require a defense of the political.

It should not occasion surprise that the significance and value of Schmitt's work are hotly contested. But there is a consensus in the growing scholarly literature on Schmitt that Schmitt's work put forward an important challenge to liberal approaches in political and constitutional theory. This challenge deserves to be taken seriously, even while Schmitt's own counterproposals are often unattractive. Schmitt's work clearly offers provocative and sophisticated discussion of a number of issues in legal and political theory – such as the nature and limits of emergency powers, the nature of constituent power, the limits of constitutional amendment, just war theory, the legitimacy of international criminal law and of humanitarian intervention – that are still the subject of extensive debate. In all these areas, Schmitt's arguments have the potential to enrich contemporary debate, precisely by going against the grain of received opinion.

Abstract

Private lives of scholars have received some attention by researchers, which is reflected in a still modest but growing body of literature. Traditionally biographies of great men have provided insights into the personal lives of protagonists predominantly as background information for their professional enterprises. Feminist historiography pointed out the interrelatedness of private and professional spheres as well as the productive roles of women in scientific collaboration. This article will discuss collaborative couples and antinepotism rules in academia as two rather well-researched areas and point out avenues for further research, also taking cues from the history of the natural sciences.

Private lives of scholars in the social and behavioral sciences is an understudied topic and remains wide open for research. Until recently authors typically focused on one person, usually a man, and concentrated their accounts on the protagonist's work. Biographies of great men frequently portrayed the female partners, if mentioned at all, as secondary, for instance in their roles of caring and supporting wives or assistants. Although literature on collaborative couples in the sciences is widely available, many of these books can be categorized as popular science accounts. While such works often pose claims of historical accuracy, they use the private lives, especially the marriages and partnerships, as a literary tool to thrill readers, and in doing so, often reproduce outdated views on gender relations. For instance, they point out the asymmetry between the man as creative and active and the woman as supportive and assisting, or they emphasize distinct spheres of action for men in the public and women in the private realm.

Historians of science, however, have shown that private and professional spheres are inseparable, and furthermore that "domestic arrangements are part of the culture of science" (Schiebinger, 1999, p. 188). Historians have also come to understand science both as a social practice and a collaborative effort. As a consequence, research has expanded from focusing on the lone genius or the big man of science to include women, assistants, family members, and lay persons. It sought to identify the actors involved and to appraise their contributions to the production of knowledge and to the scientific enterprise more generally. As historians have conceptualized gender as a social construct and historical category and originally focused mostly on women, feminist historiography was initially dedicated to including women in historical accounts and restoring them to their deserved historical place. Taken to the extreme, however, one-sided approaches risked to create accounts of great women (Eckstein, 1996; Chiu, 2008). Thus, gender has been increasingly conceptualized as an analytical tool to explore the relational character of the concept and the ways in which meanings of gender are constructed, which results in attempts to consider both genders equally (Scott, 1986, 2010).

Much of the work on private lives of scholars refers to natural scientists. While traditional biographies of big men of science used details of private events and everyday life of scientists to round out narratives of their professional lives, historians have recently cast a more analytical and productive glance at the intersection of private and professional lives. As Donald Opitz pointed out, explorations of the private realm as a site of knowledge production informing scientific endeavors have led to new interpretations of the work of scientists such as Galileo Galilei, Isaac Newton, Charles Darwin, and Louis Pasteur by revealing the psychological, personal, and social influences on their scientific work (Opitz in Lykknes et al., 2012, p. 249). This is linked to an understanding of science as a social and cultural activity and an interest in the dynamics of scientific practice rather than a focus on the successful outcomes only. This article surveys work on two aspects of private lives of scholars that have received attention by historians: first, familial arrangements and collaborative couples and, second, antinepotism rules in academia and their consequences. While the focus is on the social and behavioral sciences, examples from other disciplines serve as models for future research.

Familial Arrangements and Collaborative Couples

The roles of family members, particularly wives, in scientific activities were at the center of historians' attention, as they started to investigate the roles and activities of various actors in scientific collaboration. A long-standing perception based predominantly on published records and a historiography focused on big men of science held that, if wives were involved in their husbands' work at all, they served as secretaries or assistants, or provided a comfortable and undisturbed atmosphere for his scientific work. As historians of science such as Sally Gregory Kohlstedt and Margaret Rossiter explored the ways in which women were involved in scientific work, they revealed that women played more manifold and substantial roles in the production, communication, and application of scientific knowledge than previous literature had suggested (Kohlstedt, 1999; Rossiter, 1982, 1995, 2012). The range of capacities in which women were involved in scientific pursuits include, but are not limited to, researcher, research assistant, coauthor, editor, discussion partner, critic, typewriter, secretary, manager, fund-raiser, public relations organizer, and all the tasks

connected to running a household, taking care of the family, and being a friend and romantic partner. While this research focused on the natural sciences, some social and behavioral scientists were included. About the same time, social scientists started to uncover women's spheres of action in and contributions to their own disciplines (Deegan, 1991; Laslett and Thorne, 1997; Silverberg, 1998).

In order to interrogate systematically the intersection of private and professional lives, scientific couples became a productive unit of analysis that allowed the exploration of scientific collaboration by taking seriously the contributions of both partners in their joint endeavors. The seminal publication *Creative Couples in the Sciences*, edited by Pycior et al. (1996), probed cross-gender collaboration for different variants of collaboration and aimed at restoring women to the historical record, while neglecting, as Opitz et al. have argued, to explore "how collaboration – or, in its own case, degrees of collaboration – might be historicized and explained as products of partners' agency within particular, local contexts" (Opitz et al. in Lykknes et al., 2012, p. 3).

The recent follow-up book *For Better or for Worse?* (Lykknes et al., 2012) expanded the questions and analytical angles of *Creative Couples*. As it can serve as a model for how to approach familial collaboration in the social and behavioral sciences and for private lives of scholars more generally, it offers strategies for further research by covering a wide range of disciplines, geographical locations, time periods, and actors, and by exploring a variety of modes of collaboration between couples. The contributions in this book ask how the meanings of gender roles were negotiated in relation to each other and how these meanings change over time and vary according to historical context. Such inquiry focuses less on the outcomes and assessments of contributions, and more on processes by exploring the dynamics, negotiations, and representations of collaboration.

In *For Better or for Worse?* Per Wisselgren explored three social science couples in Sweden at the turn of the twentieth century within the context of academization of the social sciences and found different types of collaboration that he situated within 'action spaces' at the intersection of social reform and social sciences (Wisselgren in Lykknes et al., 2012, p. 196). With the husbands holding academic posts, Wisselgren found that the wives contributed to their work in varying capacities and intensity, but also worked independently on projects of their own. As opposed to the limited wives-as-assistant model, he identified three ideal types of spousal collaboration. First, the 'two roles model' describes a mode of collaboration in which family and other kinds of work can be combined, with the family having priority. Second, in the 'in the shadow of' type, the wives' interests are subordinate to the ones of their husbands. While wives made significant contributions to the husbands' work, they remained largely unacknowledged. Finally, the 'separate worlds' model describes an arrangement in which the spouses pursue their own interests independently from each other (Wisselgren in Lykknes et al., 2012, p. 209). Wisselgren's analysis broadens the scope of understanding spousal collaboration and the context in which modern social sciences unfolded. It can serve as an example of the manifold avenues open for future research to shed light on the understudied but rewarding topic of private lives of scholars. His research also cautions not to anachronistically accept the boundaries of present-day disciplines or academia more generally as a frame for analysis. Showing how particularly the women were active in social movements outside the academic realm and collaborated on what is now understood as the husbands' work suggests that a wider angle on scholarly activity has the potential to provide more comprehensive and nuanced insights not only into personal lives, but into the creation and application of knowledge.

Eileen Yeo's analysis of the Webbs, the Bosanquets, and the Branfords, three social science couples in Great Britain at the turn of the twentieth century also delineates different models of intellectual collaboration and married life (Yeo in Lykknes et al., 2012). This examination of the gendered division of labor in these marriages exemplifies diverse arrangements ranging from a traditional constellation with the man doing intellectual social science work and the woman being more practically and social-action oriented to reversed gender roles. The husbands' involvement in household issues also varied. These examples highlight not only the different possible arrangements of spousal collaboration and private life, which call for more research. They also accentuate the importance of careful attention to the historical context that conditions the options available to the couples, for example, regarding contemporary gender roles and expectations but also regarding institutional structures of social science and practice. Furthermore, as the professionalization of the social sciences in Great Britain with more extra-academic opportunities followed a different path than in the US where social science strove for academization and rigid objectivity in the early twentieth century, this context needs to be taken into account in order to detect possible spheres or action and configurations of professional and private lives. Moreover, these examples point to cross-country comparisons and transnational approaches as fruitful modes of analysis.

By and large the heterosexual married couple is the unit of analysis of scientific couples' collaboration. In his study of the British socialist, philosopher, and activist Edward Carpenter, Opitz transcended this common unit to explore the modes of collaboration of a homosexual couple. This analysis of an alternative to the normative heterosexual married couple and their social science and activism reveals that the practice and meaning of collaboration are historically contingent and need to be carefully historicized within their social, cultural, and political contexts. In his example, therefore, Opitz suggested the term 'cooperative comradeship' to describe the mode of Carpenter's domestic partnership and collaboration with his partner George Merrill (Opitz in Lykknes et al., 2012, p. 246). Following Opitz' lead to include same-sex collaboration in various domestic arrangements suggests a variety of new research that not only expands the core unit of analysis but through intersections with other historiographical themes could add new perspectives on the lives and work of social and behavioral scientists. Even though same-sex partnerships are often mentioned in passing, systematic explorations of the partners' living and collaboration arrangements are pending. For example, the

sociologist Jessie Taft and her partner of 50 years, Virginia Robinson, substantially shaped the social work program at the University of Pennsylvania, but their lives and work have not been systematically studied from a couple's perspective. Furthermore, relationships do not necessarily have to be lifelong commitments in order to be significant. They can be temporary or change character over time, as exemplified by Margaret Mead and Ruth Benedict, whose personal and work relationship also invites further research.

While collaborative couples in the same discipline or closely related fields are prevalent in literature, cross-disciplinary couples may reveal different dynamics of living arrangements and collaboration. The focus on same-disciplinary collaboration is plausible and reflects both reality and scholarly interest. On the one hand, many partners met as students, or students and teachers, or colleagues in the same department or field. On the other hand, researchers who are interested in a particular discipline are perhaps more prone to select couples from this area (Handler, 2004).

Looking across disciplinary boundaries, however, will very likely prove productive, since research at the intersection of disciplines can open a vantage point for studying cross-fertilization of different fields, of different disciplinary cultures, as well as their interactions. As historians of science have been interested in ideas and methods circulating and passing through various disciplines, being appropriated, modified, and put to use in new ways, a look at cross-disciplinary collaboration may also help to shed light on such dynamics. The lives and work of Louis Guttman, an American mathematician and sociologist, and his wife, Austrian-born geneticist Ruth Halpern, serve as a case in point (Wurzinger, 2002). After World War II, the Guttmans moved to Israel, where Louis established the Israel Institute of Applied Social Research. While Ruth continued her work in genetics, cancer research, and psychology, she also served as the senior scientist at her husband's institute. Both applied Facet Theory to their own research specialties, a concept whose development is commonly attributed to Louis. Their marriage and collaboration provides an opportunity to explore further their personal and professional roles as they pursued their own separate careers, but also collaborated, and shared a family life including three children. Coming from the US and Europe, respectively, and building their careers in Israel, this example promises an exceptionally rich and complex constellation to study, not only because of their different disciplinary, social and cultural backgrounds, but also because they did so in unfamiliar terrain, which potentially requires more intense and explicit reflexion and negotiations than the native society where role expectations and social and professional arrangements are clearer.

Modifying the units of analysis can lead to innovative new research. After the solitary individual of the past, after looking at couples, schools, and laboratory groups, more recently new modes of communication, telecommuting, and increased mobility of scholars has transformed collaboration. As Nancy G. Slack pointed out, these changes are altering both private and professional lives and are leading to more flexibility in collaboration of scholars in research networks without being at the same place physically. Current-day technology and mobility also open up new ways of organizing the balance between family and professional lives. Moreover, gender roles in society have been changing, leading to more egalitarian division of household responsibilities among couples than in the past and potentially resulting in new configurations of lives and careers for both men and women (Slack in Lykknes et al., 2012).

But even further back in history, a wider angle on collaboration yields new and productive insights. Deborah Coen (2007) has shown in her study of the extended Exner family in fin-de-siècle Vienna how private life, politics, and science intersected and, in fact, exerted strong mutual influence. Coen detailed how the activities in the Exners' semiprivate annual summer retreat in the countryside substantially influenced their scientific thinking, which manifested itself in their works in fields such as physics, meteorology, and ethology. While an extensive scientific dynasty like the Exners is rare, scientific families, even on a smaller scale, do invite further analysis. The Odum family comes to mind, with Howard W. Odum, a distinguished sociologist, and his sons Howard T. and Eugene Odum, who became two of the most eminent American ecologists of the twentieth century. The sons were lifelong collaborators and were at least motivated by their father's sociological framework and social activism, which begs the question of intergenerational transmission of (social) scientific thought, culture, and collaboration.

In a recent study of the Swedish social scientists Alva and Gunnar Myrdal, Thomas Etzemüller (2010) explored the profound entanglements and interdependencies of the Myrdals' private and professional lives. In their capacity as social engineers in Sweden they understood their own personal lives as a role model for the modern, social democratic society in whose reform they were involved. In their private lives, which they publicly displayed, they attempted to demonstrate rationality, equality, and control of emotions, which they envisioned as the main pillars of the reformed Swedish society. The negotiations and conflicts between the spouses about equality, collaboration, and the tension between individual liberty and dedication to the shared lives and work reflected the ambivalence of the larger process of modernization in society. This study of the Myrdals stands out as a model for exploring the intersection of the private and professional lives and inspires future research along similar lines.

As in the past most scholars came from educated upper and middle-class backgrounds, access to universities for larger parts of the population and policies like affirmative action in the United States, as well as efforts to increase the number of women and members of minorities in higher education have started to change the demographics of the social and behavioral sciences. This development opens up an entire new universe of experiences from different social and cultural vantage points to explore how family life is organized and how personal and professional lives are negotiated, and to study further how scholarly work is negotiated, practiced, and presented. In the mid-twentieth century, however, as large numbers of women graduated from universities and sought employment at colleges and universities, hiring policies guided by antinepotism rules profoundly affected their lives and careers as the next section explores.

Antinepotism Rules and Their Consequences

Initially implemented to base academic appointments and advancement on merit rather than on personal relationships, antinepotism regulations led to large-scale discrimination of women in particular. Instead of holding full-fledged faculty positions as appropriate for their training and experience, many highly educated women found themselves relegated to low-rank, often unstable positions with little prestige and small salaries. These disadvantages predominantly affected the women themselves, but also bore consequences for their families. A lower total family income is the obvious consequence, but the women's positions were often temporary, geographically scattered, time-consuming, and scheduled at inconvenient times. In addition to exploring the effects of antinepotism rules on women's careers, more research is needed on the consequences for the couples' relationships, for family life including children, for these families' social lives and networks. How did inferior and time-consuming jobs affect the fathers' involvement in family life? What were the reactions of the husbands, who succeeded professionally at the cost of their wives' careers while, at the same time, they valued their wives' academic skills?

Cases of stalled or diverted careers because of antinepotism rules in the United States are increasingly well documented, even though this documentation and analysis remains far from exhaustive. One prominent example is the psychologist Else Frenkel-Brunswik, who is best known for her coauthorship of *The Authoriatian Personality*. Since her husband Egon Brunswik was a faculty member at the Department of Psychology at Berkeley, she could not obtain a tenured position at the same institution. Instead, the University's Institute of Child Welfare became her institutional home, where she was hired as a research associate. In addition to maintaining a productive research agenda, she taught courses at the Department of Psychology, but without being accepted into the faculty. At the University of Kansas, the renowned psychologist Beatrice Wright was barred from teaching, because her husband was a faculty member. Her textbook on disability, however, was used in the classes she was not allowed to teach. Not least because of Wright's case, the University of Kansas reversed its policy and Wright could obtain a faculty position eventually (Rossiter, 1995, p. 141). The sociologist Caroline Baer Rose is another prominent example of the effects of antinepotism rules on women in academia. She was married to Arnold Rose, a sociologist at the University of Minnesota. Before they moved to Minnesota in 1952, both had worked on the research and the manuscript of Myrdal's *An American Dilemma*. Even though the Roses collaborated throughout their marriage and coauthored several books and articles, Arnold's position prevented Caroline from becoming a faculty member at the Department of Sociology. Thus, she held a temporary position in a small college, worked on high school curricula, taught correspondence courses, and found other ways of employment at the University. She was only able to join the faculty and become full professor after Arnold died in 1968 (Howery in Deegan, 1991).

These antinepotism regulations, even though they were applied in varying severity at different institutions, locked out highly qualified women particularly from the most prestigious universities. A study by John Parrish, a professor of labor economics at the University of Illinois, analyzing faculty numbers by field and sex at the 20 leading universities in the United States in 1960 illustrates the gender-segregation at the top ranks of academia. In psychology 5 out of 184 full professors (or 2.72%) were women (for the total including lower ranks, i.e., assistant professors and above, 30 out of 416 faculty members were women, which is 7.21%). In sociology, all of 2 women could be found among a total of 108 full professors, which equals 1.85% (the total faculty was 259, out of whom 12 were women, which translates into 4.63%). The situation in economics was similar: The total of 205 full professors included 4 women, or 1.95% (including lower ranks: 16 out of 435, i.e., 3.68%). One woman held a full professorship in anthropology vis-à-vis 46 men (2.17%), whereas the total faculty of 94 included 3 women, i.e., 3.19%. Political science had 2 full female professors out of 161 (1.24%) as opposed to 6 out of 336 (1.79%) including assistant professors and above. Finally, there was no woman among 44 full professors in geography, whereas one woman could be found in the total faculty sample of 97 (1.03%). (Parrish cited in Rossiter, 1995, p. 128ff.)

The women affected by antinepotism regulations turned to various strategies to deal with this discrimination. As one popular strategy, they took on assignments in different university departments (if allowed) or lower-rank colleges in the region. In doing so, they were at least able to work in the field in which they were interested and trained. Some tried to accumulate so many outside accolades that pressured university administrations to hire or advance them, as it was eventually the case with Beatrice Wright at the University of Kansas. Yet another strategy was not to marry at all during their active time as professionals, as did the archeologists Madeline Kneberg and Thomas Lewis (Rossiter, 1995, p. 125).

Antinepotism rules did not entirely seal off women from positions in higher education, however. Particularly lower-rank and public colleges and universities, as well as newly founded institutions tended to interpret the antinepotism rules more generously than long-standing top-tier universities. For example, both the sociologists Lewis and Rose Coser were offered professorships by the State University of New York Stony Brook, while Luther and Jessie Bernard, also sociologists, were hired by Pennsylvania State University.

By the early 1970s, more and more American universities started to loosen or reverse their antinepotism rules, not least because these rules conflicted with affirmative action policies. While there are indications that nepotism restrictions continue to exist at some colleges and universities, albeit in a more covert manner, it is the term 'dual career couples' that currently garners attention. Academic couples still often fail in their attempt to find appropriate positions for both partners in the same institution or even geographical region, and it is still mostly the women who cannot attain their professional goals. A recent project in Germany explored the internal and external conditions of the lives and work of academics that continue to adversely affect women's employment (Rusconi and Solga, 2011). While this project focused on the current situation, it can serve as a repository of themes to pursue relevant questions

in historical research on private lives of scholars in the social and behavioral sciences.

More systematic study of the intended and unintended consequences of university hiring policies and practices for the women and their spouses and families has the potential to illuminate the intersection of the personal and the professional. As research has focused on North America and more recently Germany, an international comparative perspective also seems worthwhile, as does a transnational one particularly looking at the international migrants in academia. Furthermore, research has focused on academics who, despite having faced discrimination and setbacks, were determined and tenacious enough to stay in or distinguish themselves outside academia. This viewpoint is a variant of the winner's perspective which restricts the subjects under investigation to those individuals who were eventually successful. If sources permit, in order to gain a better understanding of the processes and dynamics involved, future projects should include the lives and careers of persons who got discouraged or had no other opportunity than leave academia for different career paths.

Conclusion

As the body of literature on the private lives of scholars is modest but growing, a variety of emerging avenues for research hold the promise for multifaceted new insights into the history of the social and behavioral sciences and the experiences of scholars. Historical research depends on sources, however, and the lack of material particularly covering the personal realm is often an inhibiting factor for research. In many cases the extant papers equal the published record, which often went through a selective process that weeded out material that was not published or did not lead directly to publications. For the big men of science, records about their private lives, their wives and their shared lives and work are usually scant, and the same is true for the few famous female social and behavioral scientists. Margaret Mead stands out as an exception, since her papers also contain material on her husbands. However, researchers can take their cue from women's history, which has demonstrated how historical narratives can be revisited and revised both by reinterpreting archival material and by consulting previously neglected sources. Additionally, unconventional sources may provide starting points for further research. For instance, the protagonist in Philip Roth's campus novel *The Human Stain*, is modeled after Melvin Tumin, professor of sociology at Princeton University (Flood, 2012).

While finding and presenting new material and case studies is certainly important, it is desirable for further analysis to move toward comparative, transnational, longitudinal, and comprehensive analyses. Investigating various perspectives of private lives of scholars in the context of different cultures, disciplines, historical contextualization, and discourses will significantly enrich the historiography of the social and behavioral sciences and their practitioners.

Abstract

Ever since its beginnings at the turn of the eighteenth to nineteenth century, the modern educational system has been accompanied by alternative schools, the numbers and broad effects of which have varied over the course of the years. This coexistence is by no means based on independence, but is the manifestation of complex reciprocal relations which exist despite fundamental differences in the ideologies of the two approaches. Phases of intensive development in the domain of traditional schools have been mirrored by similar phases of intense activity in the alternative school movement; alternative schools fulfill important functions within the general spectrum of educational possibilities.

Background and Conception

Because proponents of alternative schooling are critical of contemporary manifestations of the traditional school system, the focus of their critique has shifted over time. In general, however, their criticism is based on objections to the structures and functions of the modern school. They do not restrict their demands to a return to earlier historical epochs and structures in which schools still played a minor role. Their objectives are for duress (compulsory education and instruction) to be replaced by freedom; teacher-directed schooling and instruction by self-directed action on the part of the student; the curriculum by the individual needs of the student; competition and rivalry by community; compartmentalization by wholeness and integral methods in instruction; the separation of life and school by an interweaving of the two spheres (e.g., Holzman, 1997). The fundamental criticism of traditional schooling is based on the conviction that this form of education is burdened by a basic contradiction: Although adults – and particularly adults living in modern democracies – are granted dignity, majority, and self-determination, children and adolescents at school are denied these basic rights, albeit on the pretext that they first have to learn how to exercise them. Because it is not possible to recreate the historical conditions which preceded institutionalized education and its inherent ambivalences, however, the critics of traditional schooling have to resort to so-called 'counterschool' initiatives (German: *Gegenschulen*). Although some of these are embedded in a variety of alternative organizations (e.g., flat-sharing communes, communal child care, and even dietetic measures), in general it is not society that is deschooled, but school itself. The extent to which this radical rearrangement leads to the complete disintegration of institutions is dependent on its (partly unintended) consequences.

Structural and Organizational Characteristics

Pedagogical aims are reflected in the specific organizational characteristics of any given school (e.g., the general structure of the school, the relationships between teachers, parents, and students, the organization of classes, the methods implemented). In turn, these characteristics constitute the decisive prerequisites allowing many alternative institutions to exceed the norm with regard to content and in both the pedagogical and the social fields. Indeed, the typical approach of the alternative schools can be reduced to a simple formula: in contrast to the universal institutions of the traditional system, which are characterized by high levels of internal differentiation and complicated organizational structures, alternative institutions are distinguished by social clarity and immediacy owing to the fact that they are, from the outset, geared to the particularities of their respective clients. Accordingly, the student body in an alternative school on average numbers less than 200 (cf Mintz et al., 1994). Thus, irrespective of content-related differences, the alternative school represents a special type of school or, more specifically, a type of school offering a special kind of education. While this offer may formally be an open one, it in fact only reaches the few who know how to take it up.

Due to these invisible processes of selection, alternative schools can be expected to be more or less immune to many of the problems arising in schools which really are open to all (as is made clear by the reports and evaluations of alternative schools; cf as a very vivid example Duke and Perry, 1978). In accordance with the very definition of the alternative school, however, these assets cannot readily be transferred to the mass school system as a whole. Instead of having to simultaneously meet the needs of students from different backgrounds and with various levels of qualification, alternative schools are able to respond to individual differences and developments emanating from a more homogeneous context of attitudes and lifestyles. The additional potential for motivation and identification (in both students and teachers) which is inherent in a free choice of school or in the decision to embark upon a rather unusual experiment constitutes another factor which cannot easily be transferred to the traditional school. As a rule, 'counterschools' are spared the arduous coordination of pedagogical subfunctions on the basis of a division of labor: because of the small size of these institutions, instruction and education, counseling and care all rest in the hands of a few. Instead of having to strictly adhere to general and at least partly formulated rules in order to ensure the smooth running of the

school and its classes, confidence in the closer personal ties and connections of the school community makes it possible to act more effortlessly, easily, and flexibly. Finally, the danger of merely running out of inspiration within the confines of internal school processes is reduced, as the high levels of input from the local environment mean that the system's contours remain rather diffuse. The close links between the home and the school, which are not limited to financial support, but also involve the parents' practical cooperation, can be seen as another important asset.

Developments Since the 1960s

The concepts behind alternative schooling and its implementation reach far back in time, and in some respects they refer to the founders of modern educational theory (e.g., Rousseau or Herbart). Progressive education in the United States and so-called *Reformpädagogik* in Germany, both of which emerged after the end of the nineteenth century, may certainly be considered to be phases of activity to which a number of existing institutions can be traced back (e.g., Semel and Sadovnik, 1999). However, the main wave of alternative school foundation resulted from political and social conditions including the failure or petering out of large-scale attempts at educational reform (e.g., Carnie et al., 1996); this holds especially for the Anglo-American countries since the 1960s. Most of the alternative institutions founded during this phase were set up in the United States, and the majority are still to be found there (cf Mintz et al., 1994). Although less than 5 percent of students at elementary and secondary school actually attend alternative schools, the institutions now number several thousands in the United States, most of them elementary schools. The institutions are highly divergent in terms of their targets, methods, integration of parents and students, links with the traditional system, locus of control, and circles of addressees. It would thus seem justified to focus this overview of alternative schooling since the 1960s on the situation in the United States, all the more so because both the fundamental principle of alternative schools ('as many institutions as there are needs and groups') and current trends in development (adopting the tasks of the traditional system) are to be observed there.

One important form of alternative education is home schooling (cf Evans, 1973), where parents instruct their children at home with the permission of the state. If – as is quite often the case – these children meet up with other home students in (elementary) schools on single days of the week, there is a sliding transition to school cooperatives aiming at unconstrained, playful, spontaneous learning in open instruction. Other institutions specifically target problematic cases, so-called at-risk students, including not only chronic truants and low-performing students, but also talented nonconformers (in the broadest sense). A well-balanced program of drill and freedom is intended to render school attractive again, thus helping these students to enhance their performance.

However, this development has also led to a reverse trend, a sort of back-to-basics shift to formal 'three Rs' schools, which specifically emphasize the basic skills, discipline, and respect for the authority of parents and teachers (cf, e.g., Deal and Nolan, 1978). Similar trends are to be observed at the secondary level. The large number of schools-within-schools – smaller, less complex units running different experimental programs, and affiliated to larger state schools – is particularly notable. The spectrum also includes schools attempting to set themselves up as 'just community schools' based on the principles of Kohlberg's developmental theory (cf Kohlberg, 1985). The so-called 'schools without walls' represent another form of alternative education. They not only offer a 'normal' curriculum (differing from that of the traditional school in terms of content and time), but give students the opportunity to learn in the adult world. This is intended to provide students with extrascholastic experience and to enable them to prove themselves in the world of work. Although this approach initially seemed very promising, experience has shown that it is in fact very hard to put into practice.

Recent Trends and Perspectives

Over the past few decades, there have been signs of a kind of division of function and labor between the traditional and the alternative schools in the United States. This has been expressed in an increase in the state-controlled administration of alternative institutions. The fact that such large numbers of US alternative schools were founded at the beginning of the 1980s is probably related to this development. The radical free schools (e.g., Dennison, 1969), which signaled the upheavals of the 1960s and certainly provided considerable impetus for subsequent developments, play a lesser role in today's broader stream of initiatives. The basic conceptions and expectations of alternative schooling have also been affected, resulting in the extremely short lifespan of some of these institutions. There is still a great deal of fluctuation, making it hard to make valid evaluations of these institutions (cf the data in Mintz et al., 1994: p. 10ff.). Even the early approaches and experiments demonstrated the great weaknesses and dangers of such institutions – the cost of their structure-related advantages (cf also Swidler, 1979). Critics have reduced this to the polemic formula that precisely those principles and premises which allowed the pure 'counterschool' initiatives of the early period to emerge later threatened their ability to survive. Wherever the concept of freedom as a counterpole to the compulsory character of the traditional institutions went hand in hand with systematic shortcomings in the specification of learning targets, there was the risk that later conflicts be all the more severe due to the differing hopes and expectations of those involved (cf Barth, 1972: especially p. 108ff). When every school-related action was dependent on the consensus of every single member of the school community, the school's fate was put in the hands of changing minorities with the power of veto, all the more so when the small size of these private institutions kindled fears of sudden financial ruin. Allowing almost all of those concerned to take an active role in the decision-making process did not in fact ensure the equality of all participants – instead of increasing the capacity to solve problems, there was a growing risk of disappointment, and the necessary basic consensus was threatened by frequent conflicts and failures in minor matters. The firm and wide-ranging commitment of parents, extending well into issues of classroom practice, often

resulted not so much in the enhancement as in the disturbance of school activities. Teachers were consequently made to feel insecure and were put on the defensive instead being provided with support and control. Attempts to simultaneously cope with the factual demands, organizational affairs, and personal standards inherent in these institutions – preferably without referring to preset guidelines – led to the systematic overexertion of those concerned, and the end of many 'counter-schools' was marked by the burnout of the teaching staff (Dennison described this phenomenon as early as 1969). The unconditional openness with respect to the other members of the school community and the intimacy of the small group responsible for the school meant that factual disputes often escalated into personal trials. Moreover, school affairs were often overshadowed by secondary motives such as parental self-realization or the search for security.

By integrating and promoting alternative schools, the state aims to increase the diversification of the educational spectrum, to enhance the overall efficiency of schools (which has been subject to criticism for decades; cf, e.g., Goodlad, 1984), and to better meet the specific needs of certain problem groups in both school and society. The US programs of community schools, magnet schools and, more recently, charter schools provide evidence for this trend, and are looked upon with growing interest by other countries as possible models for the resolution of system-related problems. However, more detailed analyses of these models point to significant limitations in their problem-solving capacity, limitations which are ultimately rooted in the basic concepts of market and choice (cf Lauder et al., 1999). The community schools program has already been thwarted by the US authorities' desegregation measures: although these schools were directed at the advancement of members of the underprivileged minorities, most of whom are colored, they undermined the desired objective of racial integration. Magnet schools were supposed to be a free choice of school with a special educational program which acted like a magnet, attracting students from beyond the racial boundaries marked out in residential areas and school districts. They were intended to promote racial integration, which can scarcely be achieved through the compulsory measure of busing. A number of objections have been voiced against this school form. For example, it is argued that the enlargement of catchment areas weakens the link between the school and the parental home. Furthermore, although magnet schools may well establish a balanced relation between whites and blacks in their own student bodies, there are too few magnet schools to ensure social compensation on a large scale.

Moreover, there is an imperceptible shift in their circle of addressees: instead of reaching the underprivileged, out-of-school colored population with their specific educational provision, magnet schools in fact seem to appeal to white parents and their children who would otherwise switch to private schools or the more privileged suburbs (cf Smrekar and Goldring, 1999).

The charter schools, on the other hand, which in a way transfer the principles of the private school (i.e., the autonomy of schools and a free choice of school) to the state school system, are faced with comparable problems on a different level inasmuch as unforeseen side effects have been revealed in the social process. Despite the fact that the numbers of charter schools have increased considerably over the past few years, they are still far from ever being able to constitute the majority of state schools, belonging by definition to the optional domain of educational provision. The half-hearted legislative reservations perceptible in most of the federal states against according too many privileges to these schools threaten to render the entire charter program futile (cf Hassel, 1999).

School Achievement as Moderated by Sociodemographic Status: The US Case

Selcuk R Sirin and Taveeshi Gupta, New York University, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

School achievement is greatly moderated by sociodemographic factors, such as socioeconomic status, minority status, students' gender and grade level as well as the location of schools. Based on a comprehensive review of the literature, the effect of socioeconomic status on school achievement is illustrated with empirical evidence.

School achievement has been defined as the degree of students' academic learning. Assessment of the existence, extent, or depth of such learning is conducted by using a number of measurement tools across research, policy, and interventions; the most commonly used indicators are grades in math, science, and reading, standardized achievement tests, and IQ tests. Although high correlations are reported among these various measures of academic performance, they also capture a unique aspect of individual student learning. For instance, achievement tests are specifically designed to measure efficiently the amount of knowledge and/or skill a person has acquired at school using a comparison with a standard or norm that is usually based on an expected level of mastery in a content area. Often these tests are used to measure and compare students, schools, districts, and states, based on norm-referenced scales of achievement. Similarly, IQ tests are intended to assess general cognitive competence, rather than measuring learning in a particular area of schooling.

While these are the most widely used ways to assess school achievement, many problems have been found with the use of these tools. A comprehensive review of literature using the meta-analysis technique compared the average correlations between socioeconomic status (SES) and school achievement as measured by different types of assessment tools (Sirin, 2005). The measures of assessment include verbal achievement, math achievement, composite achievement, grade point average (GPA) for all subjects, and IQ scores. The findings from this meta-analysis show that most studies used verbal achievement measures, followed by math achievement, IQ, composite achievement, and GPA scores. Although IQ tests are sometimes included as a measure of academic competence, there has been an ongoing dispute about the use of IQ tests in educational research. Opponents of using IQ tests have identified evidence of a bias against various disadvantaged groups, such as minorities and women. Using grades as the measure of achievement can also be quite problematic, particularly when making comparisons across studies, because grades awarded by teachers are usually considered more subjective than standardized achievement tests.

School Achievement and SES

The relation between SES and school achievement is one of the most widely replicated findings in educational research. SES refers to one's position in society as it is determined by a variety of factors including income, education, occupation, and accumulated wealth (Bollen et al., 2001). Conceptually, the social and economic conditions of children provide the physical, social, and intellectual background for effective learning (Coleman et al., 1966). It is important to note that while social class refers to a more unidimensional construct, SES refers to a more multidimensional conceptualization of social and economical characteristics (Bollen et al., 2001). SES plays two roles in the educational process both of which may exert influences on school achievement, both directly and through associated behaviors and experiences. The first aspect of SES includes resources, such as parental education, income, and wealth and the second aspect of SES includes 'social capital,' i.e., social status as a function of relative positions in a hierarchy, such as social class. While the first aspect to a great extent dictates life conditions for students by determining the share and quality of life to which they have access, the second aspect provides membership in a certain social class that creates its own personal socialization processes, through which the schooling behaviors are acquired (Coleman, 1988). The family's level of educational values, expectations, and school-related activities in the home is partly determined by their SES. In other words, families from different SES groups create different learning environments that affect the child's academic achievement. Hence, the impact of SES on school achievement is not solely due to the amount of parental income or parental education, but also due to social capital that is composed of ideas, behaviors, attitudes, values, and language.

Overall, educational research has been consistent in its finding that SES has an impact on students' school achievement (Coleman et al., 1966; Sirin, 2005). Coleman et al.'s (1966) report ('The Equality of Educational Opportunity'), is widely considered the most significant education study of the past century. James Coleman, the head of a large team of scholars from various fields was commissioned to write this report by the US Office of Education in accordance with the Civil Rights Act of 1964. Using data from over 575 000 students and their teachers at 4000 schools across the United States, the team examined how differences in various types of physical, human, and social resources across schools related to average school achievement levels.

In their final report (which is usually referred as *the Coleman Report*), Coleman and his colleagues presented four major findings: (1) for all ethnic groups, the strongest predictor of achievement was the family's SES (parental education, parental

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23102-4

income, etc.); (2) for students who were not White, the SES of the school as assessed by its percentage of White students and the average economic background of all students, was the second best predictor of school achievement; (3) teacher characteristics assessed by educational degree and teaching experience was a modest but significant predictor of school achievement only for the school performance of African-American students living in the South; and, (4) once all the above characteristics were controlled, school-based economic characteristics, such as per-student spending and instructional resources, had little or no effect on school achievement (Coleman et al., 1966).

Although the Coleman report made it clear that the social composition of the school, the student's sense of control of his or her environment, and the verbal skills of the teachers were relatively related to school achievement, the biggest contribution of this report is its first finding. The report's overall message that family SES is the most important predictor of academic performance has challenged educational researchers and policy makers ever since its publication. At a time when civil rights were on top of the agenda for many, the report's findings that academic achievement was less related to the quality of a student's school and more related to the student's family background was received with controversy, as it suggested that inequities in economical resources allocated to schools had little or no influence on school achievement.

Many scholars criticized the report and pointed out a number of methodological shortcomings of the study (see Buchmann and Hannum, 2001; Murnane, 1975). A major area of dispute was that the study failed to portray accurately the way schools operate, by conceiving of schools as a kind of a closed production facility with school and family resources at one end and student achievement at the other. Therefore, the study did not sufficiently assess the possibility that school achievement might vary between schools as a function of student characteristics, such as race, gender, or urbanity. Students within the same school may not share equal access to the school resources such as tutoring, library, guidance services, or access to the most experienced teachers; and they usually experience difficult educational experiences due to certain groupings based on their characteristics. Further, studies showed that in poorer countries, the impact of the school and the teacher on achievement was greater than family characteristics (Buchmann and Hannum, 2001). Despite these shortcomings, the Coleman Report nevertheless boosted research on SES and schooling processes (Wong and Nicotera, 2004).

Sirin (2005) conducted the last and most comprehensive meta-analytic study that reviewed the literature on SES and academic achievement, most of which was published after the Coleman Report. The results of this meta-analysis clearly show that the significant impact of SES on student's academic achievement is as strong today as it was when investigated by Coleman et al. (1966). Sirin found that based on 78 independent samples, the overall correlations effect size (ES) was 0.29, which reflects a medium level of impact. This general finding in the Coleman and Sirin studies has been confirmed by many other large-scale surveys. For example, the 1985 National Assessment of Educational Progress (NAEP) report on reading found that 17-year-olds from low-income backgrounds could read only at an elementary school level (a level achieved by advantaged students at age 13). The national results in 2009 from the NAEP show that there were no significant changes from 1992 to 2009 in the reading score gaps between White and Black students or between White and Hispanic students. Likewise, demographic data show that retained students tend to come from lower SES backgrounds than nonretained students. It has been shown that approximately 40% of repeaters come from the lowest SES quartile, whereas approximately 8.5% come from the highest SES quartile. Research also shows that adolescents who come from lower SES families are more likely to drop out of high school and less likely to attend college (Gándara et al., 2004).

Recent research shows that SES is not only 'directly' linked to school performance, but also that its impact is multifaceted. For example, students from lower SES backgrounds are more likely to lack basic academic skills even as early as kindergarten, which puts them at risk for failure in later years of schooling (Levin and Belfield, 2002). They are also more likely to be at risk for poorer health and nutrition, which could affect their ability to concentrate in the classroom (McLoyd, 1988). Students coming from low SES families also tend to have less access to both social and cultural capital that helps them navigate systems crucial to educational success (Wadpole, 2003). Moreover, families from low SES backgrounds are more likely to live in poor neighborhoods, with larger number of family members in a household, with fewer educational and social resources available to both parents and student for help toward academic success (Duncan and Magnuson, 2005).

Minority Status, SES, and School Achievement

Minority status continues to be a critical demographic factor in educational achievement. Recent surveys conducted by the National Center for Education Statistics (NCES) indicate that the achievement gap between minority students and their White peers, measured by various subject tests and the Scholastic Aptitude test (SAT), has remained the same over the last two decades. Research with Latino/a students, for example, have found that Latino/a youth earn lower grades than other ethnic groups and are at increased risk for dropping out of high school. There is also a persistent achievement gap between African-American and White students, and African-American students are under-represented in classes for the gifted, and over-represented in special education classes (Lleras, 2008). Many factors have been suggested to explain the lower academic achievement of minority students, but the major explanation has been the fact that minorities or disadvantaged families usually live in harsher social and economical circumstances. On average, minority students are more likely to live in low-income households or in single-parent families, more likely to attend under-funded schools, and their parents are likely to have less education – all of which are components of SES and linked to school achievement (Brooks-Gunn and Duncan, 1997). Moreover, research shows that minority students may face discrimination and prejudice at school and the value systems of school may be in conflict with some of their cultural values. In other words, race and ethnicity intersect with SES so

that much of the effect that race and ethnicity have on school achievement may be actually due to the influence of SES.

The moderating role of race in the relation between SES and race in relation to school achievement is still being debated in educational research. There is mixed evidence when studies attempt to untangle the effect of ethnicity versus SES on achievement. On the one hand, some studies show that race/ethnicity, and not the family SES of students, has a stronger influence on school performance for minority students. Catterall (1998), using national longitudinal data, found that within African-American cohorts, SES does not have an influence on their school performance. Similar findings were also found in ethnographic investigations which show race as the most consistent and strongest predictor of school achievement above and beyond SES. Moreover, despite recent national surveys indicating that although the gap in the parental educational level of minorities, particularly between Blacks and Whites, narrowed substantially during the last three decades, there is still a continuing achievement gap between minority groups and Whites.

On the other hand, a number of studies have found the opposite – that it is SES and not race/ethnicity that carries most of the variance in school performance among minority students. For example, Blair et al. (1999) investigated achievement differences across ethnic groups using two waves of a national data set and found that SES-based characteristics were the best overall predictors of academic performance above and beyond minority status. Similarly, other studies have found that regardless of their race/ethnicity, middle class students had higher school achievement than White students who came from working and underclass backgrounds. Likewise, Howell and Frese (1982) illustrated that dropout rates for White students are actually higher than those for minorities, after controlling for SES. There is no agreement at this point as to how to interpret these contradictory findings, partly because for minority students in the United States, race/ethnicity and SES are deeply linked.

Sirin's review shows two separate findings that provided empirical evidence for the role of race/ethnicity and SES on school achievement in the United States. First, a comparison of White only samples with minority only samples showed significant differences between the groups. More specifically, family SES was a stronger predictor of school achievement for White students than for minority students. Additional evidence that minority status acts as a moderating factor came from the significant association between the percentage of minority students and the magnitude of the correlations between SES and school achievement. It was seen that as the proportion of minority students increased in a sample, the magnitude of SES-school achievement correlation decreased significantly. Put differently, the more minority students in a sample, the lesser the impact of SES on school achievement. Based on these findings, it is fair to suggest that minority students do not benefit from their family background as much as White students do.

The finding that family background variables such as parental education, income, and occupation are less predictive for minorities should be of concern not only for reasons of future research methodology, but also for social policy implications. Research suggests that neighborhood and school SES may exert a more powerful effect over and above family SES on academic achievement within minority communities, particularly within African-American communities. For example, Gonzales et al. (1996), using a 1-year prospective design, examined the combined effect of family and neighborhood influences on the school performance of African-American high school students. As expected, they found that family SES variables were not as predictive of school achievement, but neighborhood risk factors were related to lower grades and also moderated several other factors such as parenting support and control. In a large scaled examination of the same issue, Dornbusch and Ritter (1991) also compare the differential effects of parental SES and neighborhood SES in relation to school achievement. They showed that the ability of family SES to predict school achievement is minimized when students, regardless of their ethnic background, live in a census tract with a substantial proportion of minority residents. In other words, the reduced influence of family SES on school achievement among African-Americans is not because of their ethnic background, but because most African-Americans and fewer Whites live in neighborhoods with various higher risk factors for school success. Therefore, neighborhoods with disadvantaged communities may lack the resources necessary for school achievement and neighborhood SES is an important factor to be considered.

SES and Gender Differences in Achievement

Sex and gender (analogous to race) have been cited as factors that influence the relation between SES and school achievement. Unlike sex (that is understood to be the biological and physical characteristics of an individual), gender is socially constructed via processes that can vary with SES. In recent years, the recognition of gender differences in school achievement has led investigators to incorporate gender into research on the impact of social and economic factors on the academic performance of students.

In 1992, the report of the American Association of University Women (AAUW) titled 'How Schools Shortchange Girls' pointed out that it has only been in the past two decades that scholarly work on the effect of gender differences in school achievement has become popular. Despite progress in closing the gender gap in many domains, current research shows a number of significant gender differences in school achievement. The majority of the research has focused on differential math performance between boys and girls. It is reported that girls score higher, on average, than boys on tests of verbal abilities; while boys consistently score higher, on average, than girls on tests of science and spatial abilities. One limitation of the research examining gender gaps is that it usually focuses on early adolescence, because studies show that boys and girls have similar achievements in mathematics in the early grades but that boys tend to improve their math scores, relative to girls, as they move through school.

By finding that boys consistently achieve higher scores in math and science and that girls score higher in reading and writing, the research seems to suggest that external social factors are operating beyond biological correlates to explain this difference. The question of whether or not these differences are

changing due to SES received very limited attention in the literature. For example, in line with the observation of the AAUW report that gender was not a salient variable, White's (1982) meta-analysis did not include any variable to account for gender differences. Similarly, in the 2012 Recommendation to the NCES report on 'Improving the Measurement of Socioeconomic Status for the National Assessment of Educational Progress,' Cowan et al. do not mention gender as a differentiating variable in the measurement of SES.

Therefore, based on separate studies on the impact of gender and SES differences on school achievement, it is plausible to argue that students' gender may moderate the relation between SES and school achievement. In other words, one could argue that the social and psychological pressures experienced by a girl from a lower SES family might be very different from those experienced by a boy who comes from a lower SES family, stemming from the differing cultural expectations operating on a girl or a boy.

Sirin's analysis of gender as a moderator of the relation between SES and school achievement was not significant. Based on independent samples (i.e., all-girls samples and all-boys samples), the impact of SES on school achievement was not significantly different for the two gender groups. Likewise, a second analysis found that the proportion of girls in the sample as a possible moderator of the correlation between SES and school achievement was not significant, indicating that the proportion of girls in a sample was not significantly associated with the magnitude of the correlation between SES and school achievement.

Students' Age, SES, and School Achievement

Yet another important factor affecting the social and economic circumstances of school achievement is the developmental stage of the students. Since the impact of contextual factors is time variant, they lead to questions about the impact of SES on school performance over time. One of the major developmental questions is whether the relation between SES and school achievement varies over the developmental stages, from early childhood to late adolescence. Questions of a developmental nature ask whether the impact of SES that occurs in early schooling is different from the impact of SES in later years at school. Furthermore, scholars examine whether various components of SES (e.g., income, education, and occupation) take on different weights in their relation to school achievement at different ages.

Longitudinal studies that measure SES from early childhood to adolescence have only recently begun to be investigated, so it is difficult to know the answers to these questions from the existing literature (McLoyd, 1988). In one of the few existing studies, Duncan et al. (1994) look at how family SES impacts school achievement over time and found that the preschool years are periods of increased risk for school achievement in poor children. Duncan et al. investigated the Panel Study of Income Dynamics and showed that poverty during the first 2 years of life has a much more negative impact on educational attainment than poverty during middle childhood and adolescence. Similar trends can be seen in the school transition literature which shows that students from lower SES backgrounds present an especially sharp drop in school performance after the transition to junior high school. Likewise, the impact of being economically disadvantaged is seen even within developmental stages. In their study of over 21 000 children from kindergarten to third grade using the Early Childhood Longitudinal Study, Kindergarten Class of 1998–99, Aikens and Barbarin (2008) find that higher SES relates to higher initial achievement in the fall of kindergarten and more rapid reading growth per month across elementary years.

In Sirin's meta-analysis, students' grade level was found to be a significant moderator of correlations between SES and academic achievement with an ES of 0.19 for kindergarten students, 0.27 for elementary school students, 0.31 for middle school students, and 0.26 for high school students. Thus, with the exception of the high school students, there seems to be a trend of increasing ES from kindergarten to middle school. Thus, it can be concluded that the developmental stages moderate the effect of SES on school achievement, at least until middle school.

Single Parenthood, SES, and School Achievement

Family structure has long been considered one of the key aspects of family background that may affect various developmental outcomes of children, including academic performance and achievement. There are two important reasons for considering family structure in the measurement of SES. Firstly, family structure is usually considered as an indicator of social and economic circumstances because single-parent families generally have lower incomes than two-parent families. Secondly, in addition to economical decline in family income, single-parent families also have less resources for parental involvement, which creates another possible link to lower achievement.

Over the past three decades, large-scale national surveys indicate that students who live in single-parent families are more likely to be placed in special education classes, to have lower grades, are less likely to be in school at age 17, and less likely to graduate from high school than students who live in two-parent households. A similar trend was observed in achievement tests; younger students who come from single-parent households score significantly lower on achievement tests than those who come from two-parent families.

Despite the evidence that links single parenthood with low academic achievement, several investigators have moved away from this deficit model and pointed to a shift in the impact of single parenthood on school performance. For example, the national trends between 1970 and 1990 showed that on comparing single-parent households and two-parent households in conflict, some of the characteristics of single-parent households are indeed conducive to school success. Sustained conflict within a family can significantly affect children's development, and children who live in single-parent families resulting from divorce are probably much more likely to have been exposed to this detrimental environment in their original family. Thus, for these children, the transition to a single-parent family may not have direct negative consequences, and, in some cases, might even create a better developmental environment.

Furthermore, the drop in SES due to parental breakup probably does have a negative effect on academic achievement; but because mothers are more educated in recent years as compared with the 1970s, the impact of single parenthood on children is not as detrimental as once assumed. Therefore, once other family differences are accounted for, the lack of a direct effect on achievement from being in a single-parent family cannot be extrapolated to imply that children who live in a nonconflictual or positive two-parent environment would do as well in a single-family environment.

Sirin's meta-analysis showed that the proportion of single parents in a sample does not significantly moderate the magnitude of the relation between SES and school achievement. The results of his study, therefore, do not support the notion that family structure moderates the impact of SES on school achievement. Despite the fact that these results were based on a small number of studies, the insignificant finding is still worth noting because the current literature on the impact of single parenthood is inconclusive. On the one hand, many studies in the past reported that students reared by single parents tended to do worse in school, while on the other hand, analysis of national data and other studies found no negative impact of the single-parent background, particularly after controlling for family SES. In fact, Duncan and Magnuson (2005) suggest that interventions that are designed to increase parents' SES (by improving single-parent education levels) will provide perhaps a modest increase in achievement for children. Instead, they call for policies that directly target children's aptitude or mental and physical health. Thus, the conclusion that families headed by single parents were a source of disadvantage is brought into question by findings from the meta-analysis.

School Location, SES, and School Achievement

One of the moderators of the effect of SES on school achievement that is tested by researchers is that of school location. Data from the NAEP, for example, indicated that the achievement of children in affluent suburban schools was significantly and consistently higher than that of children in 'disadvantaged' urban schools (U.S. Department of Education, 2000). Clearly then, the location of a school is closely related to the social and economic conditions of its students. Therefore, there is some indication that rural–urban–suburban difference may actually be another indication of differences in students' SES background.

'Location, Poverty and Schools,' a study by the U.S. Department of Education (1996) showed that SES is an important factor in accounting for differences in the achievement gap across urban, rural, and suburban schools districts (e.g., the higher the levels of poverty, the lower the levels of achievement). Urban children were more likely to be living in poverty than those in suburban locations – 20% compared with 11% in 2011. Therefore, unless SES was held constant, no findings of rural–urban difference are meaningful on their own.

Interestingly, even after accounting for SES, there seems to be a number of significant differences between urban, rural, and suburban schools. Urban schools on average have larger enrollments but less funding for their schools than suburban schools. Moreover, research suggests that students at urban schools are more likely to present higher rates of student behavior problems such as absenteeism, classroom discipline, and student pregnancy than nonurban schools. Since urban schools are also more likely to cater to immigrant populations, students in urban schools are also more likely than those in other locations to have difficulty in speaking English and are subject to numerous health and safety risks that present greater challenges to their school performance. Beyond student level, teacher absenteeism was more of a problem in urban schools than in rural or suburban schools. Finally, urban schools had fewer resources available for teachers and schools and teachers had less control over their curriculum than suburban or rural schools, at both the elementary and secondary levels.

The variable of geographical location of schools in the studies reported in Sirin's meta-analysis was found to be a significant moderating factor. Students who go to urban schools seem to have higher disadvantage in terms of the impact of family background on school achievement than students in suburban schools. The difference between the correlations across the groups was significant and large, indicating that the geographical location of the school is a strong moderator on the impact of family SES on school achievement. One of the reasons why geographical location seems to have such a strong effect on the impact of SES on school achievement is due to the fact that the location of the school largely determines the amount of financial resources available for students. In a nationwide study of over 17 000 school districts, investigators have found that higher neighborhood SES, as measured by the value of owner-occupied housing or by residents' educational attainment, is significantly related to greater school expenditure per student. In addition to this nationwide analysis, several statewide surveys showed the same phenomenon, in which differential resources were available for schools in different locations. For example, an examination of data from Virginia shows that resources are associated with a school district's SES characteristics and that resources were related to students' academic achievement. Such discrepancies in funding allocation continue to plague the educational system even today. These findings further illustrate that the relation between SES and school achievement is moderated by geographical location.

The finding that the impact of family SES on school achievement was the weakest for urban schools compared with nonurban schools should be interpreted in the context of the economical desegregation of people. According to U.S. Department of Education's (1996) report, many school outcome measures were largely the same across urban, rural, and suburban schools, once the percentage of students in poverty was controlled. This is an important factor to consider when interventions are aimed at improving child outcomes nationally.

Conclusions

The quest to assess the relationship between SES and school achievement produced a wealth of research, from which it is clear that SES continues to influence students' performance in

school. The observed magnitude of this influence, however, depends on several sociodemographic factors. Minority status, age, and family structure of the student, all affect the correlation between SES and school achievement. Finally, contextual factors as determined by the geographic location of the school and the percentage of minorities in the school, change the magnitude of the relation between SES and school achievement.

School Achievement: Motivational Determinants and Processes

Friedrich-Wilhelm Schrader and Andreas Helmke, University Koblenz-Landau, Landau, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Among the many factors that influence school achievement, motivation plays a major role. Motivational approaches are classified using a framework based on expectancies and values. The role of some important motivational theories (self-related concepts, attribution, interest, goals and goal orientations, avoidance) to achievement is outlined, followed by two integrative models (Eccles' expectancy-value model, process models of learning, and self-regulation). The focus is on motivational constructs that aim at explaining learning and achievement in schools. For most motivational constructs, effect sizes from meta-analyses are reported. Finally, complex relations among motivation and achievement are discussed.

School achievement (SA) – its structure, determinants, correlates, and consequences – has always been a major issue of educational psychology, especially effectiveness of teaching and learning. Interest in achievement as a central outcome of schooling has considerably increased during the last two decades. In particular, large-scale projects like Progress in International Reading Literacy Study, Trends in International Mathematics and Science Study, and Program for International Student Assessment had and still do have a strong and enduring impact on educational policy, as well as on educational research, and have also raised the public interest in scholastic achievement. Among the many determinants of SA, motivation is presumably the one that is given the most attention by laypersons, teachers, and parents. In educational psychology, much research has been done on motivation and many motivational constructs that are important for understanding learning processes were explored. But few studies, especially longitudinal studies that include different student characteristics and indicators of classroom context as predictors of achievement, have examined the direct links of motivation to SA. Recently, syntheses of meta-analyses of factors contributing to achievement were published by Hattie (2009, 2012). This work includes motivational factors and so can give an overview of the empirical relations between motivation and achievement. The aim of this article is to address the role of motivational variables with respect to scholastic achievement. We refer to achievement as a result of individual learning processes in school classrooms, and consequently, focus on research that is especially useful for classroom learning.

SA and Its Determinants

SA refers to cognitive learning outcomes of students that are products of instruction or aimed at by instruction within a school context. Cognitive outcomes mainly comprise not only procedural and declarative knowledge but also problem-solving skills and strategies. Student achievement is measured by tests or by teacher judgment, i.e., grades. Research on SA is typically faced with a multilevel problem, that is, for conceptual and statistical reasons, the individual student's level has to be separated from the classroom level, school level, and even higher levels (Helmke and Weinert, 1997). In this contribution, we focus on achievement at an individual level.

Achievement as a result of classroom learning is typically a product of cumulative learning, i.e., an accumulation of specific learning processes and opportunities during extended periods of time – for instance, a school year (Helmke and Weinert, 1997). Research on determinants of achievement, then, deals with the question if and to what degree long-term achievement can be predicted by variables that are assumed to influence achievement, with context, instructional processes, and individual student characteristics such as intelligence, prior knowledge, or motivation as predictors. One line of inquiry is based on large-scale classroom studies and longitudinal designs and is correlational. Motivation is often measured by questionnaires that have been developed for different constructs, and improved measurement has led to many advances in this field (Graham and Weiner, 2012). Training studies, which are experimental or quasi-experimental, constitute another type of research. While this kind of research often takes place within classroom, basic research on motivation that seeks to clarify motivational processes and mechanisms as well as mediational processes relating motivation to learning processes has used laboratory studies. Results summarized in meta-analyses mostly deal with the individual difference perspective, whereas models and theories of motivation often focus on processes and mechanisms.

Achievement is multidetermined, which means that it is influenced by many different factors simultaneously (Helmke and Weinert, 1997). **Figure 1** shows a theoretical model that represents important determinants of SA. Individual motivational determinants include not only task-specific factors such as expectancies but also broader goals and values. Motivational factors are embedded in a complex system of individual, parental, and school-related determinants and depend on the given social, classroom, and cultural context. As shown by this model, individual characteristics have a direct impact on learning activities and achievement, whereas the effect of the other determinants, such as teachers' or parents' influences on learning and achievement, is only indirect and mediated by processes at the level of the individual learner.

Cognitive determinants such as intelligence and prior knowledge account for high portions of individual differences in SA, with an overall effect size of 0.67 (Hattie, 2009). Intelligence and prior knowledge represent the individual determinants that

 http://dx.doi.org/10.1016/B978-0-08-097086-8.26055-8

Figure 1 Interplay of individual motivational and other determinants of school achievement.

show the strongest associations with achievement, and so may serve as a reference. With respect to educational outcomes, an effect size of $d = 0.2$ can be considered as small, $d = 0.4$ as medium, and $d = 0.6$ as large (Hattie, 2009: p. 9). Cognitive factors are strongly intertwined with motivational factors, such as subjective competencies and beliefs, and a combination of cognitive and motivational factors characterizes complex processes such as self-regulation and learning strategies.

Motivation and Scholastic Achievement: A General Framework

Motivation deals with why a behavior occurs, and, therefore, deals with the factors that initiate, direct, energize, maintain, and terminate a behavior (e.g., Graham and Weiner, 2012). Expectancies and values are constituent elements of many kinds of human motivation. A person's propensity to choose a behavior depends on the value the consequences of this behavior have for the person, and the expectation or subjective probability that these consequences are met. Different approaches can be subsumed under two basic questions a person may ask before deciding to act: (1) Can I do the task? This question refers to the expectancy component that covers self-concept and related constructs (such as self-efficacy, subjective competence). (2) Do I want to do the task? This question deals with the value of a task (task values) and addresses the importance or personal significance of consequences. Following Eccles and Wigfield (2002) and others, we use expectancies and values as a basic framework to give an overview over motivational constructs that are relevant for achievement. In addition, we present two integrative approaches: (1) expectancy-value models that combine expectancies and values, and include antecedent conditions and achievement; (2) process models of learning activities and self-regulation.

There is considerable conceptual overlap among different theoretical approaches of motivation. Graham and Weiner (2012) characterize motivational approaches and constructs in more depth by using additional questions. A basic distinction is between extrinsic and intrinsic motivation ('Why am I engaging in this activity?'). Whereas many theories of motivation focus on behaviors that are instrumental for certain incentives or goals, the behavior in itself may have intrinsic value. Attribution theory covers causal explanations ('Why did I succeed or fail?'), which are often raised after finishing an action. Emotions ('How do I feel?') are important constituents of motivation and represent motivational factors on their own (see Pekrun et al., 2007, for an overview over emotions related to achievement). Because emotions are broad constructs that require a more detailed presentation, we do not include them in this article.

Motivation refers to factors that influence decision-making and forming of intentions. But in order to achieve a goal, motivation is not sufficient. Decisions and intentions have to be transformed into actions, which often are complex behaviors extending over long periods of time as is characteristic for learning activities. In this case, some kind of external or internal regulation (planning, monitoring, feedback) is required. From the standpoint of an individual learner, self-regulatory or volitional processes ('How am I doing?') should take place. Theories that combine motivation and cognition and include self-regulation and volition as factors supporting effective goal attainment represent a more complete framework (Eccles and Wigfield, 2002).

Constructs Relating to Expectancy

Self-Concept

Self-related cognitions characterize the interplay between cognitive abilities and beliefs (see **Figure 1**) and, therefore,

play an important role in the domain of education. Self-concept is a general and comprehensive construct that comprises cognitions and beliefs about one's abilities and academic achievements (academic self-concept, self-concept of ability), but also social and physical characteristics. Self-concept has an affective component, commonly termed as self-esteem, and a behavioral component, which corresponds to self-efficacy. According to Marsh et al. (2012), a distinction between the cognitive and the affective component does not seem to be fruitful in empirical research. In present conceptualizations, self-concept is often conceived as hierarchically ordered, with general self-concept or self-esteem at the top, self-perceptions in different domains at an intermediate level, and self-perception of specific task behaviors within a domain at lower levels. Whereas social and physical self-concept is important for psychological health and well-being, self-concept of ability (largely equivalent with academic self-concept, subjective competence, achievement-related self-confidence, expectation of success) is relevant to learning and achievement.

The relation between self-concept and achievement is well established. In meta-analyses, effect sizes ranging from 0.32 to 0.41 are reported (Hattie, 2009, 2012). Correlations between domain-specific self-related cognitions and achievement are substantial whereas achievement is unrelated to general self-esteem and nonacademic components of self-concept (Marsh et al., 2012). Correlations are especially high, when self-concept is conceptualized as domain-specific, and when pupils are older (Helmke and Weinert, 1997). What is, yet, controversial is the causal ordering between self-concept and achievement. Research based on longitudinal assessment and structural equation modeling of both self-concept and achievement has demonstrated that self-concept depends on former achievement (skill-development model) but also predicts subsequent achievement (self-enhancement model) (Helmke and van Aken, 1995; Marsh et al., 2012). That is, self-concept is a motivating factor, but also reflects the impact of prior achievement on beliefs and cognition. Therefore, achievement and self-concept should be considered as mutual reinforcing influences. Furthermore, both variables are important success criteria of schooling, so, from a practical view, ameliorating both of them is an important goal (Marsh et al., 2012).

Self-Efficacy

Self-efficacy, which is theoretically and empirically related to self-concept, has a clear motivational focus and, though also influenced by former achievement, predicts subsequent achievement. Self-efficacy refers to beliefs in one's capabilities to organize and execute the courses of action required to produce given attainments, i.e., to solve a problem or accomplish a task. Self-efficacy is a task-specific construct, relating to a specific situation, and not a general expectation. How much it may generalize across different tasks and situations is an open question (Bong and Skaalvik, 2003). With respect to achievement, meta-analyses report effect sizes of 0.37 (Hattie, 2009), and correlations with academic achievement in the range of 0.49–0.70 reported when self-efficacy corresponds closely to the criterion task (Schunk and Pajares, 2009).

Self-efficacy is assumed to influence choice of activities, effort, and persistence. Self-related cognitions may influence scholastic performance by means of various mechanisms: Students with a high self-concept of ability initiate learning activities more easily and more quickly, show more persistence and less procrastination behavior, are more apt to continue learning when a task is unexpectedly difficult, and are better protected against interfering cognitions such as self-doubt and other worries (Helmke and Weinert, 1997).

But the self-concept–achievement relation may depend on classroom context. Weinert and Helmke (1987) found that self-concept predicted achievement of 5th graders when teacher support was low, but lost its predictive power when teacher support was high. This is interpreted as a kind of functional compensation between self-concept and instruction.

Implicit Theories of Intelligence

The impact self-related cognitions have on learning and achievement depends on the view persons have about the nature of their capabilities, especially their general intelligence but also their domain-specific abilities (Dweck and Master, 2009). Implicit theories either constitute an entity theory or an incremental theory, both having different motivational consequences. A person with an entity theory believes that intelligence or ability is a fixed attribute that cannot be changed and task performance reflects this ability. As a consequence these students are concerned about their intelligence. When involved in tasks, they are motivated to demonstrate their intelligence by successful performance (performance goals). Failure suggests a lack of intelligence, and students wish to avoid such a situation, which may threaten their self-esteem. Effort, which is not a salient causal factor for these students, is considered as useless, or even worse, as damaging because failure in spite of effort suggests low ability. An incremental view of intelligence means that intelligence is seen as changeable and open to improvement by effort. Students with an incremental theory of intelligence consider tasks as an opportunity to learn and improve their abilities (learning goals). Dweck and Master (2009) discuss several consequences of these different motivational tendencies with respect to students' goals, learning opportunities, effort, reactions to failure, self-esteem, and performance. Implicit theories of intelligence seem to have an effect at critical points in one's life when new demands arise and increased effort is required. Blackwell et al. (2007) demonstrate achievement gains for students with an incremental theory of intelligence over 2 years of junior high school whereas students with an entity theory do not gain.

Attribution

Attribution theory that can be traced back to the classical model of Weiner (Graham and Weiner, 2012) deals with causal factors

to which success and failure are attributed. These are internal (ability, effort) and external (task difficulty, luck) causes, which may be more or less stable or controllable. As a consequence, it is psychologically favorable when failure is attributed to controllable factors such as lack of effort, and unfavorable when failure is attributed to stable and uncontrollable factors such as ability. Attributions of success and failure influence expectations for success and failure in future. In control theory, a basic distinction is between internal and external locus of control. Meta-analyses show effect sizes of 0.23 and 0.36 for internal locus of control and of 0.56 for success versus failure attributions with respect to achievement (Hattie, 2009).

Constructs Relating to Values

Motivation to Learn and Attitude toward Learning

Motivation to learn is a general construct that comprises subjective expectations as well as incentive values (anticipated consequences like pride, sorrow, shame, or reactions of significant others, the incentive of learning action itself, i.e., interest in activity). For the impact of motivation to learn on achievement, a moderate effect size of 0.34 has been reported. Attitude toward learning means the affective (negative or positive) aspect of the orientation toward learning that corresponds to the value component of learning motivation. Attitude can refer to school or school subjects. For attitude to school subjects, meta-analyses have demonstrated effect sizes of 0.32 for science and of 0.29 and 0.47 for mathematics (Hattie, 2009). There are several more or less interrelated concepts that are associated with the subjective value of the domain or subject under consideration, the respective activities, or on a more generalized level, teachers and school.

Intrinsic Motivation and Interest

Intrinsic motivation is defined as motivation to engage in a task or activity for its own sake whereas with extrinsic motivation engagement occurs for instrumental reasons, such as reward (Linnenbrink and Pintrich, 2002). Intrinsic motivation theories comprise self-determination theory, flow theory, and interests (Eccles and Wigfield, 2002). Self-determinations theory is a theoretical approach that specifies conditions leading to intrinsic motivation. Intrinsic motivation is promoted when people feel competent, self-determined (autonomy), and experience a sense of relatedness (Graham and Weiner, 2012). Flow is the immediate subjective experience of fluent and mentally absorbing processes that occurs when people are engaged in an activity that can be mastered (Eccles and Wigfield, 2002). Studies that explore that actual role of intrinsic motivation for SA are rare. Gottfried (1985) reported moderate correlations between academic intrinsic motivation measured by a self-report inventory and test achievement and teacher grades for reading, language, and mathematics in grades 4–8.

Interest can be considered as a special kind of intrinsic motivation that is related to specific objects, subject areas, or activities (Schiefele, 2009). A basic distinction is between individual, or personal, and situational interest, which corresponds to the well-known distinction between trait and state. Individual interest is a general and relatively enduring affective-evaluative orientation toward certain subject areas or objects, situational interest is a temporary state aroused by specific features of an object. Individual interest comprises feeling-related and value-related valences. The former relates to the feelings that are associated with an object or activity, the latter to the personal significance or importance of an object or activity. As summarized by Linnenbrink and Pintrich (2002), personal interest is positively associated with achievement, the use of deeper cognitive strategies, and increased attention and persistence. For the relation between interest and achievement, an effect size of 0.65 has been reported (Hattie, 2009). Köller et al. (2001) found in a longitudinal study that interest had a significant effect on the development of mathematical achievement from grade 10 to 12 but not from grade 7 to 10. That is, motivation played a role in higher grades when instruction is less structured than in earlier grades. This result illustrates the role of context for motivation.

Goal Orientations and Goals

Achievement goals refer to the purpose why persons engage in achievement behavior. Mastery, learning, or task-involvement goals are distinguished from performance, relative ability, or ego-involvement goals (Maehr and Zusho, 2009). The former are characterized by a tendency to develop one's own competencies and skills, the latter by a tendency to compare one's achievement with that of others and outperform other persons. Mastery goals often are seen as favorable to learning, and performance goals as detrimental (Maehr and Zusho, 2009). But the role of achievement goals is more complex, depending on achievement indicators (grades, test scores), age, and other moderators. In many studies performance goals were related to higher grades, especially for older students (Linnenbrink-Garcia et al., 2008). Furthermore, many researchers considered it necessary to distinguish between performance approach and performance avoidance goals (three-factor model), or to combine mastery and performance orientations with approach and avoidance tendencies (four-factor model). As was demonstrated in a recent meta-analysis based on 151 studies, the overall relation between goals and achievement is rather weak: ranging from $r = 0.13$ for mastery goals in the traditional two-factor model to $r = -0.13$ for performance avoidance goals in the four-factor model (Huang, 2012).

Beyond general orientations like mastery and performance goals, individuals strive for a diversity of goals (Boekaerts, 2009; Eccles and Wigfield, 2002) that compete for limited resources. Little is known about goal coordination and the conditions under which alternative goals are supportive or debilitating. Goal conflicts can arise, for example, between academic goals and leisure time goals. Different cultures differ in the degree goal conflicts play, which are especially high in individualized Western countries (Hofer et al., 2010).

Avoidance Motivation

For many students, achievement is aversive or, at least, ambiguous. Achievement motivation comprises two general

motives: Hope for success and fear of failure. Self-related cognitions play an important role: Students expect failure, because their subjective competence is low (or because they are uncertain about their competence); and they fear failure, because failure has negative consequences for their self-esteem and the worth they have for persons such as parents, teachers, or peers. The self-worth theory of achievement motivation (Covington, 1984) views ability and effort as causal factors for achievement. Ability is a highly valued attribute and is inferred from successful performance that is achieved with low effort. On the other hand, effort is a risk because failures, in spite of high effort, lead to the inference that ability is low. To avoid these results behaviors like procrastination or self-handicapping may result.

Integrative Approaches

Eccles' Expectancy-Value Model

One of the most elaborate models is Eccles' expectancy-value theory (Eccles, 2005). In this model, expectation of success and subjective task value which directly predict achievement-related choice and performance are linked to anteceding factors. Proximal antecedents include goals, self-schemata, and self-concept. Distal factors are stable person characteristic such as gender and aptitudes or cultural milieu. Four components of task value are distinguished: attainment value (i.e., the perceived importance of doing well), intrinsic value (i.e., how much enjoyment the individual derives from the task), utility value (i.e., how the task relates to future goals), and costs (i.e., what the individual has to give up to engage in a task) (Eccles and Wigfield, 2002). Eccles's model has been tested intensively with a focus on achievement related choice (career choice, course plans, enrollment decisions). Whereas choice is mainly predicted by the value component, achievement seems to be directly related to performance expectancies (Wigfield et al., 2009). A further important result is that expectancy and value judgments are positively associated (Eccles and Wigfield, 2002).

Contrary to the multiplicative model originally used in motivation research, Eccles' expectancy-value model is an additive model. In a recent classroom study using a large sample of 2.508 students and complex statistical techniques Trautwein et al., (2012) not only confirmed that expectancy beliefs were a stronger predictor for achievement than value beliefs, but also found significant interactions between expectancies and values. These results suggest that the full model including a multiplicative termin could be more appropriate than the additive model although a proof of interactions is difficult in most cases.

Process Models of Learning and Self-Regulation

The influence of motivation on achievement is mediated by learning activities with engagement and concentration as indicators of effective learning. Meta-analyses for engagement in science and concentration on achievement with effect sizes of 1.09 and 0.61, respectively (Hattie, 2009) demonstrate the significance of these factors.

Managing one's own learning activities is indispensable for higher learning processes and the acquisition of a rich and elaborated knowledge base. Self-regulation comprises different approaches focusing on cognitive, metacognitive, and motivational processes, and is characterized by a cyclical structure that is based on a goal, self-initiated behaviors toward that goal, feedback, and reactions depending on feedback.

Zimmerman and Labuhn (2012) distinguish three phases: a forethought phase (task analysis, goal setting, strategic planning), a performance phase (task strategies, self-instruction), and a self-reflection phase (self-judgment, monitoring). These processes are influenced by specific forms of motivation. During the foresight phase, key motives are goal orientation, self-efficacy, interest, and task values; during self-reflection, causal attributions and self-evaluative judgments such as self-satisfaction and affect come into play. Effect sizes for training programs related to self-regulation such as teaching metacognitive strategies (0.69), study skill (0.59), self-verbalization, and self-questioning (0.64) are at least moderate (Hattie, 2009). But in some cases large effect sizes could be demonstrated. For self-regulated interventions for math, reading and writing with primary and secondary school students effect sizes that are in a range from 0.87 to 1.44 are reported by Zimmerman and Labuhn (2012). But in school learning, learning activities always represent some mixture of external regulation and self-regulation, especially for younger and less able students (Corno and Snow, 1986). As Figure 1 shows, teachers and instructional processes as well as parents' expectations and behaviors influence learning. Furthermore, classroom teaching, and, to a minor degree, parental support constitute contexts that differ in structure and so offer different opportunities for self-regulated learning (Helmke and Weinert, 1997).

According to Boekaerts and Corno (2005), volitional aspects are emphasized in some models of self-regulation. To understand why some people – in spite of sufficient motivation – fail to transform their learning intentions into correspondent learning behavior, approaches that include volition based on theoretical work by Heckhausen, Kuhl, Gollwitzer and others (see Heckhausen and Heckhausen, 2008) have proven to be helpful. Action control refers to the ability to protect intentions against competitive tendencies, and action versus state orientation is a disposition that relates to individual differences to regulate cognitions, emotions, and behaviors in order to accomplish intended actions. While direct links between action-state orientation and achievement have rarely been explored, some studies could show that implementation intentions were associated with academic achievement (Hattie, 2009). But relations between volitional constructs and achievement are complex and mediated by many intervening processes so that more complex modeling is required.

Conclusions

Meta-analyses show that associations between motivation and achievement are moderate, sometimes rather weak, contrary to popular views of the role of motivation. But these moderate

associations may underestimate the significance of motivation for several reasons as listed below.

- Effect sizes reported in meta-analyses do not provide a complete picture if variability is not taken into account. Exploring this variability and mediating factors in more detail can suggest conditions under which stronger associations result and can lead to theoretical clarification and elaboration.
- As Figure 1 shows, motivation is only one of several important determinants of achievement. Motivational research has identified different approaches. Although most of them are conceptually related they focus on different factors. Which of them come into play, may differ and depend on student personality as well as on context.
- Motivation, in a strict sense, deals with decision-making and forming of intentions. But in order to achieve a goal, actions have to be performed, often over extended periods of time. With respect to achievement, learning activities have to be carried out. All these actions and activities require some kind of regulation and volitional processes.
- The impact of motivation is related to students' age for, at least, two reasons. First, processes such as forming an ability concept, understanding the compensatory relation between ability and effort, the use of strategies and metacognitive competences depend on cognitive development. Second, the impact of motivation varies with respect to context, and contexts differ for younger and older students.
- The role of context for motivation is as follows: Younger students are given fewer opportunities to choose and perform tasks on their own, and so the role of motivation may be more limited. The potential influence of motivation will be higher when the contexts allow or demand self-regulation. Otherwise, with strong external control such as classrooms where learning is completely structured and supported, motivational factors may lose their impact.
- Finally, research of motivation in educational contexts often uses questionnaire data that assess explicit motives. But some theorists regard implicit motives as equally important, and explicit and implicit motives may not be associated (see Heckhausen and Heckhausen, 2008).

In spite of these limitations, motivational factors are crucial for understanding learning and achievement. From a theoretical perspective, motivational and volitional processes are essential steps in a chain of processes leading from tasks to achievement but their significance depends on many other factors. In many cases, one cannot expect direct, linear relations and simple correlations between motivational and volitional characteristics and SA, but complex interactions and manifold possibilities of mutual compensation, e.g., of inefficient learning activities by increased effort. For example, excellent performance requires high degrees of both ability and effort, whereas with normal or average achievement, lack of ability can be compensated (as long as it does not drop below a critical threshold value) by increased effort (and vice versa). There is a dynamic interplay between SA and its individual motivational determinants: SA is affected by motivation, e.g., self-concept, and affects motivation itself. From this perspective, SA and its determinants change their states as independent and dependent variables.

During the last decades, a number of promising approaches and constructs were developed that make important contributions to understand the role of motivation for school achievement. As the relations between motivation and school achievement are complex, more research is needed to explore the conditions under which motivational variables have an effect upon school achievement in more detail. Models that link motivational constructs with antecedent and subsequent factors such as Eccles' model (Eccles, 2005) or the model depicted in Figure 1 could represent an appropriate framework. In future research, a broader range of stable personal characteristics such as aptitudes should be explored. Furthermore, school achievement as the main dependent variable is not a uniform construct but comprises various kinds of knowledge ranging from factual knowledge and simple skills to strategic knowledge. The effect of motivation on school achievement is mediated by learning activities and volitional processes which also should be explored in more detail. Context plays an important role to specify the conditions under which motivation is effective. One context is the learning environment which can offer different degrees of support. A highly structured supportive learning environment puts low demands on self-regulation and motivation (Corno and Snow, 1986). To understand the impact of motivation for learning in schools in more depth, the role of instruction and the interplay between instructional support and learners' activities should be considered. To examine these relations, longitudinal studies as well as experimental research are needed.

Motivation is important for life-long learning, knowledge acquisition, and self-regulation, which are basic requirements in modern societies. Self-regulation and motivational orientations that promote achievement are highly valued educational goals. This is especially true for older students but the acquisition of these skills and orientations begins much earlier (Wigfield, 1994). So, for younger children, developing motivational orientations, learning strategies and self-regulatory skills which are favorable to learning is of great importance, even if the full impact of these achievements may show up only later in their development.

Abstract

School as a social system describes schools as institutions and suggests a model of analysis that addresses the complex and often contradictory purposes of schooling. In particular, this article examines the socialization effects of schools in terms of norms, sanctions, and rites of passage and analyzes how allocation is structured within schools and between schools. The conclusion suggests that the social systems of schools may change dramatically in the future because of technological and social changes outside of the school.

School as a Social System: Introduction

A social system is characterized by an interdependent network of subunits, a defined population, an identifiable configuration of social relationships, and a distinctive culture (Parsons, 1951). While we generally think of social systems as encompassing whole populations, institutions can also be thought of as social systems because they are structured by many of the same characteristics associated with larger social systems. Seen in this light, schools can be considered as social systems complete with their own established configuration of social relations, distinctive cultures, norms, and legal obligations (Gordon, 1957; Parsons, 1959; Smelser, 1988).

To understand how the social systems of schools are created, developed, and influenced larger social systems requires a nuanced understanding of the complexity of schools. They are designed to promote learning, but they also reproduce existing social relations with regularity. They are sites of cooperation, but also of conflict. Schools are also embedded in larger social systems; society precedes schools but schools help shape society. This reflexive and interactive relationship means that schools act as conserving institutions as well as agents of change.

The missions of schools are multiple and not always aligned with the publically stated purposes of schooling: The manifest purpose of a school's social system is student learning, socialization, and allocation according to merit. In reality, the manifest purposes of schools are accompanied by a host of latent purposes such as the transmission of privilege and creation of shared norms that may have little to do with the formal curriculum or may be in conflict with the manifest purposes of schooling.

Viewed in this light, we can see that the social systems of schools are capable of producing apparently contradictory outcomes; the process of maximizing student achievement may run counter to the process of ensuring the reproduction of privilege, the elevation of the intellect may be subverted by the evaluation of material success. Schools are complex societies that when viewed analytically reveal a great deal about the larger social system in which they are embedded.

In schools there is a well-defined authority structure and a system of rewards and punishments. Schools are not bucolic societies where authority is exercised solely for the purpose of student learning. The sociologist of education Willard Waller (1932: p. 11) described the social system of schools as "despotisms in a state of perilous equilibrium." The social systems of schools are dynamic environments where conflict creation and conflict resolution are arrayed on a continuous line of human interaction.

The social system of schools includes more groups than students. Parents; teachers; administrators; custodial and security staff; local, regional, and national educational authorities; public servants; the media; and the public-at-large all participate either directly or indirectly in the social system of schools. Recently, the integration of the new communications technologies into teaching and learning has caused the social milieu of schools to expand to include people and organizations far from the physical location of the school.

The Purposes of Schooling

Schools are purposeful societies; they are social systems that are goal directed with observable and measurable outcomes. In general, there are four major purposes of schooling: intellectual, political, social, and economic (Bennett and LeCompte, 1990: pp. 5–21).

The intellectual purposes of schooling are to teach basic cognitive skills such as reading, writing, and mathematics; to transmit specific knowledge (e.g., in literature, history and the sciences, etc.); and to help students acquire higher-order thinking skills such as analysis, evaluation, and synthesis.

The political purposes of schooling are to inculcate allegiance to the existing political order; to prepare citizens who will participate in this political order; to help assimilate diverse cultural groups into a common political order; and to teach children the basic laws of society.

The social purposes of schooling are to help solve social problems; to work as one of many institutions, such as the family and religion to ensure social cohesion; and to socialize children into the various roles, behaviors, and values of the society. This process is referred to as socialization.

The economic purposes of schooling are to prepare students for their later occupational roles and to select, train, and allocate individuals into the division of labor. The degree to which schools directly prepare students for work varies from society to

society, but most schools play at least an indirect role in the process.

While these purposes are in many ways aligned in structuring schools as social systems, they may also come into conflict. This inherent tension was expressed clearly by the educational historian Laurence Cremin (1977: p. 37):

> Schooling – like education in general – never liberates without at the same time limiting. It never empowers without at the same time constraining. It never frees without at the same time socializing. The question is not whether one or the other is occurring in isolation but what the balance is, and to what end, and in the light of what alternatives.

Schools are complex societies. Intellectual creativity is not necessarily aligned with the political purposes of schooling, and social purposes of schooling are not always meant to serve the economic purposes of schooling. Understanding how these complex configurations make meaningful patterns requires a theoretical perspective.

Two Theoretical Perspectives

Not all scholars would describe schools as social systems in the same way. Structural functionalists see schools as socializing students into mainstream societal values, providing students with a common culture and language, enabling and encouraging completion of an education cycle, and preparing students for the labor market. Central to the structural functional perspective is that schools, as social systems, seek equilibrium. When the social system of the school is disrupted it accommodates to change by finding a new stable state. There is a tendency in this theory to emphasize the reproduction of existing social relations as a smooth process according to agreed-upon norms (Durkheim, 1956; Parsons, 1951).

A conflict theoretical view presents a different viewpoint. Conflict theory argues that schools are theaters of competition for status, wealth, and power. Social change is inevitable in the conflict perspective because unequal access to power, prestige, and resources inherently leads to destabilizing conflict. In this perspective, schools are social sites where conflict is continuous, power relations are legitimized or delegitimized, and the reproduction of inequality is disguised by the creation of sorting and selecting mechanisms that appear to be meritocratic, but in fact are based on race, class, and gender (Bowles and Gintis, 1976; Collins, 1971; Cookson, 2013).

These two perspectives provide alternative narratives for understanding schools as social systems. Both theories consider the major purposes of schooling to be socialization and allocation but draw different conclusions about the relationship of school to society and about how schools operate as social systems.

Socialization

Socialization in schools has been studied extensively (Coleman, 1961; Dreeben, 1968, Kerckhoff, 1972; Kohn, 1976; Willis, 1977; Lareau, 2003). Socialization is the process by which students internalize the values of the school and by extension the larger social system. These internalized values become norms that structure behavior.

Norms

Dreeben (1968) identified four norms of particular significance in industrialized societies: independence, achievement, universalism, and specificity. He explains (Sadovnik et al., 2012: pp. 131–132):

> In speaking of independence, achievement, universalism and specificity as norms, I mean that individuals accept the obligations, respectively: To act by themselves (unless collaborative effort is called for) and accept personal responsibility and accountability for their conduct and its consequences (independence); to perform tasks actively and master the environment according to standards of excellence (achievement); and to acknowledge the right of others to treat them as members of categories often based on a few discrete characteristics rather than on the full constellation of them representing the whole person (universalism and specificity).

Sanctions

The internalization of norms does not happen automatically or without resistance on the part of some students. Sanctions are applied to ensure that the norms of the school are internalized. School-based socialization is enforced by a system of rewards and punishments. Systematic regimes of rewards and punishments are generally codified in a written form and enforced by a school's academic personnel.

In theory, sanctions range in severity in proportion to the severity of the offense. Minor offenses, such as being occasionally late for class, might warrant a warning by a teacher or principal whereas cheating, drug use, or carrying a concealed weapon might warrant expulsion and in some cases criminal prosecution.

Sanctions are often applied unevenly despite their codification. Because schools educate the young and are dynamic human environments, if all failures to follow rules automatically resulted in sanctions there would be little time for instruction as students resist authority in many small and sometimes large ways that are overlooked by school authorities.

In addition, sanctions can vary by the social class and race of students. In a school educating poor and minority students, a minor drug offense might result in mandatory expulsion due to 'zero-tolerance' discipline policies, whereas the same offense in a middle-class school is more likely to result in a call to the student's parents.

The enforcement of norms, however, is not solely a function of formal rule enforcement. For the school to function as a stable social system, the majority of students (and adults) must internalize the norms of the school as their own value system. This occurs through systematic socialization in which school members internalize the dominant values of the school. This process of internalization is not left to chance, but encoded into the rituals, routines, and rationales of daily life. Students pass through an elaborate socialization experience which can be thought of as a rite of passage.

Rites of Passage

A rite of passage is a ceremony marking a significant transition in an individual's or a group's life. Rites of passage may be short or extended; for socialization purposes, extended rites of passage are most effective because they allow for repetition and permanent internalization. Rites of passage are transformative and enduring. In this sense schools are organized to produce certain types of graduates. According to Kamens (1977: pp. 217–218):

> Schools symbolically redefine people and make them eligible for membership in social categories to which specific sets of rights are assigned, e.g., income. The social organization of schools is major symbolic index of the kind of socialization that has occurred the thus legitimates the conferral of specific status rights.

By undergoing an organized set of socially sanctioned and enforced collective social experiences, students develop collective memories, shared prejudices, and social attitudes that remain with them into adulthood.

Two Interpretations

From the structural functional perspective, socialization allows for the intergenerational transmission of the shared norms required for the stability and continuity of society; from a conflict perspective, the deep internalization of school norms can lead to powerlessness and alienation. For structural functionalists, the internalization of norms is the foundation of a cohesive society; for conflict theorists the deep socialization that occurs in schools primarily serves the powerful who benefit from schools that reproduce people with differing status rights.

Allocation

Schools act as one of society's most efficient sorting and selecting mechanisms. These allocation mechanisms have consequences for students in terms of securing future educational opportunities and employment. Schools do this in a number of ways.

Within-School Allocation

Schools sort and select students according to measured abilities or skills. In theory, this type of allocation matches students' courses of study commensurate with their abilities and most likely educational and career destinations (Gamoran et al., 2000; Hallinan, 1994; Oakes, 1994; Lucas, 1999). Within-school allocation is commonly known as tracking.

While tracking can be found at the elementary level, most tracking occurs at the high school level. In the United States, students typically are assigned to academic, vocational, and general tracks. Students assigned to an academic track take college-preparatory courses, those assigned to the vocational track take skills- and job-related courses, and students assigned to general courses are offered low-level courses and skills courses. Research indicates that there is a strong correlation between track assignment and class and race (Oakes, 1985).

By allocating students to tracks, schools effectively channel them into prescribed life chances. By and large, working-class students end up in vocational tracks and middle-class students in academic tracks. Studies show that students placed in 'high-ability' tracks spend more time on actual teaching and learning activities; are able to use more interesting materials; and consistently receive better teachers, better laboratory facilities, and more interesting extracurricular activities than do their lower-track peers (Oakes, 1985; Goodlad, 1984). It has been found that track placement directly affects cognitive development (Rosenbaum, 1976).

Between-School Allocation

Schools vary in their academic and social power. Much of this differentiation is based on the social class and racial composition of families who send their children to a particular school (Coleman et al., 1981; Finn, 2009; Cookson, 2013). It is common place in educational research to ignore the social power of high schools under the assumption that years of schooling is the major allocation outcome variable of importance.

However, in the United States, the barriers to academic promotion are low in most cases and in some cases nonexistent. Because of this, the amount of schooling a student secures may not be directly related to upward mobility, but where a student goes to school, or his or her educational route, may be highly correlated to future success. Educational route determines with whom a student goes to school, the nature of his or her socialization experiences, and the social power of the credential with which he or she graduates in the transition to higher education and career (Cookson and Persell, 1985; Cookson, 2013).

Two Interpretations

For structural functionalists, within-school tracking is a mechanism for matching the talents of students to their most likely educational and career futures. In this view, tracking is not discriminatory; differentiations based on differing capacities are one of the key purposes of schooling (Parsons, 1951). Discussions of the legitimacy of allocation based on the social status of schools are generally not featured in structural functionalist literature.

For conflict theorists, schooling tends to reproduce social systems (Apple, 1995; Golden, 2007; Persell, 1977; Rothstein, 2004; Sacks, 2007). In this view, schools play a leading role in legitimating inequalities by conflating merit with ascription.

The efficacy of these rivaling perspectives is not just of academic interest; they bear directly on the meaning of equality of educational opportunity. If in fact students are allocated by factors that have little to do with achievement and merit, then the legitimating manifest purposes of education are open to question.

Conclusion: A Social System in Flux

In the last two decades, science and technology have undergone a major transformation. We are living in an age of invention

and discovery. To what degree will schools change and to what degree will their social systems change? Will technology alter the structure of education and in doing so alter socialization and allocation practices? Will schools evolve into institutions without walls? Will the socialization function of schooling include interactions with peers across the world? Will the power to allocate students be weakened by increased access to the World Wide Web?

There are those who predict that schooling as we know it today will disappear and a new era of freedom of information and global communication will undo traditional notions of schooling. Individuals will be able to chart their own educational courses without having to submit to formal schooling. In this scenario, individual agency will undermine the institutions of schooling. Schools will cease to operate as social systems.

This remains to be seen. Social structure is much like steel; it is marginally flexible but keeps its shape under a great deal of strain. Will schools as social systems change dramatically in the foreseeable future? This will remain an unanswered question for some time to come as a great deal depends on what happens in the larger society. But uncertainty is no barrier to inquiry; the subject of school as a social system is likely to remain as important tomorrow as it is today.

School Burnout and Engagement: Lessons from a Longitudinal Study in Finland

Katariina Salmela-Aro, Cicero Learning, University of Helsinki, Finland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article presents recent findings on student school burnout and engagement in light of the ongoing FinEdu longitudinal data. Schoolwork engagement is conceptualized as study-related vigor, absorption, and dedication, whereas school burnout is defined as exhaustion, cynicism, and inadequacy as a student. First, the role of school burnout and engagement are presented in the context of the demands–resources model. Accordingly, high school demands lead to burnout, while high personal and school resources lead to engagement. Burnout in turn is connected to later depressive symptoms, and engagement to later overall satisfaction with life. Second, taking a person-oriented approach to burnout and engagement, different burnout–engagement profiles in the high school context are presented. Third, the role of educational transitions in gendered school burnout trajectories is examined. Next, school burnout and engagement are considered in relation to different social contexts. Finally, an intervention program aimed at increasing preparedness for possible setbacks in the educational career and promoting later engagement and decreasing burnout is described. These recent findings are then discussed in the context of the 4-C (channeling, choice, coregulation, compensation) life-span model of motivation.

Introduction

School burnout is a new concept (Salmela-Aro, 2012), particularly when compared to research on school engagement (Newmann, 1991; Skinner et al., 1990), which has increased dramatically over the past few years (Appleton et al., 2008; Fredricks, 2011; Fredricks et al., 2004). A recent search of PsychInfo yielded 1100 hits for studies on school engagement (Upadyaya and Salmela-Aro, 2013). Engagement has also been compared to flow (Shernoff et al., 2003), a state of mind in which the student is so intensively involved in an activity that nothing else seems to matter (Csikszentmihalyi, 1990). The burgeoning interest in engagement reflects the increasing attention shown in positive psychology, where the focus is on human strengths and optimal functioning (Reschly et al., 2008) rather than on weaknesses and malfunctioning (Schaufeli et al., 2002a; Seligman and Csikszentmihalyi, 2000). However, school burnout is also a very important influence on school achievement and mental health.

In this article, first, the role of school burnout and engagement are presented in the context of a demands–resources model. According to the model, high school demands lead to burnout, whereas high personal and school resources lead to engagement. The latter is connected to later overall satisfaction with life, whereas burnout leads to later depressive symptoms. Second, taking a person-oriented approach to burnout and engagement, different burnout–engagement profiles within the high school context are described. Third, the role of educational transitions with regard to gendered school burnout trajectories is summarized. Next, school burnout and engagement are considered in relation to different social contexts. Finally, the results of an intervention program with the aim of increasing preparedness for possible setbacks in the educational career and promoting later on engagement and decreasing burnout are described. These recent findings are then discussed in the context of the 4-C (channeling, choice, coregulation, compensation) life-span model of motivation (Salmela-Aro, 2009).

The results presented in this article are based on longitudinal data drawn from the ongoing FinEdu study in which data have been collected on all the young people resident in a medium-sized town in central Finland. They have been followed intensively for 10 years, starting at age 15 (year 2003), when they were at the end of comprehensive school, to age 25 (year 2013).

School Burnout and Engagement

School burnout is a school-related stress disorder that can be described along three dimensions: exhaustion, cynicism toward school, and a sense of inadequacy as a student (Salmela-Aro et al., 2009). Cynicism is manifested in an indifferent or distal attitude toward schoolwork in general, a loss of interest in schoolwork, and not seeing it as meaningful. Inadequacy refers to a diminished sense of competence, achievement, and accomplishment as a student. Earlier FinEdu results showed that all three dimensions were stable from ages 15 to 19 (Parker and Salmela-Aro, 2011). Furthermore, both exhaustion due to school demands and cynicism toward school predicted feelings of inadequacy as a student later on (Parker and Salmela-Aro, 2011).

Schoolwork engagement, like work engagement (Schaufeli et al., 2006), can be defined along three dimensions: energy, dedication, and absorption (Salmela-Aro and Upadyaya, 2012, under review; Schaufeli et al., 2002b; Upadyaya and Salmela-Aro, 2013). Schoolwork engagement resembles flow, which describes an experience that is so enjoyable in itself that people desire it, even at great cost, purely for its own sake (Csikszentmihalyi, 1990). The main difference between the concepts of school engagement and flow is that flow refers to a short-term peak experience, whereas engagement is a more persistent state of mind. Of the three dimensions of engagement, energy refers to high mental resilience while studying, a willingness to invest effort in one's schoolwork, and a positive approach to school (Salmela-Aro and Upadyaya, 2012;

Schaufeli et al., 2002b). Dedication is characterized by a sense of significance, enthusiasm, pride, identification, and inspiration regarding school, as well as perceiving schoolwork as meaningful (Salmela-Aro and Upadyaya, 2012; Schaufeli et al., 2002b). Absorption is characterized by behavioral accomplishments and flowlike experiences, such as being fully concentrated and happily engrossed in one's studying so that time passes quickly (Salmela-Aro and Upadyaya, 2012; Schaufeli et al., 2002b). These three dimensions of school engagement are separate but highly correlated constructs (Salmela-Aro and Upadyaya, 2012; Schaufeli et al., 2002b). Developmental changes seem to co-occur in the composition of these engagement dimensions (Salmela-Aro and Upadyaya, 2012). At the beginning of postcomprehensive education, when students have experienced the transition to high school (i.e., academic track) or vocational school (i.e., vocational track), their engagement is perhaps better described as overall engagement with school. However, in their postcomprehensive education and especially in university-level studies, engagement is characterized by the separate dimensions of energy, dedication, and absorption (Salmela-Aro and Upadyaya, 2012; Schaufeli et al., 2002a,b). These changes may be due to the closeness of the transition to working life, a time when students become more oriented toward work and the new demands of working life. It is at this point when students' schoolwork engagement becomes more differentiated and similar to work engagement (Salmela-Aro and Upadyaya, 2012).

The Demands–Resources Model in the School Context

One new approach to examining school burnout and engagement in the school context is based on the demands–resources model (Salmela-Aro and Upadyaya, 2014). The demands–resources model, typically applied in studies on work engagement, suggests that high engagement in the educational setting promotes students' subsequent well-being, life satisfaction, personal growth, and learning (Demerouti et al., 2001; Salmela-Aro and Upadyaya, 2014), whereas burnout predicts problems later on. The demands–resources model assumes two processes (Demerouti et al., 2001): an effort-driven energetic process of overtaxing and wearing out in which severe study demands exhaust the student's energy and lead first to burnout and then to diminished mental health, for example in the form of depression. The other is a motivational process in which the availability of resources leads to engagement and fosters later life satisfaction. According to the demands–resources model, several resources such as high self-efficacy, and demands such as study challenges and overload, promote or hinder one's engagement over the school years (Demerouti et al., 2001; Salmela-Aro and Upadyaya, 2014).

We documented pathways from study demands and study resources to later schoolwork-related engagement and burnout and then to later life adjustment on the basis of the FinEdu data (Salmela-Aro and Upadyaya, 2014). In the model, study demands are seen as presenting a challenge to study-related goals, while resources are seen as functional in achieving study-related goals. For example, study-related stress can be interpreted as a demand felt by students that they adjust to school, whereas high self-efficacy may function as a resource for their engagement with school (Vasalampi et al., 2010). In line with the demands–resources model, study-related resources constituted more robust determinants of engagement with schoolwork, while study demands constituted more robust determinants of school burnout. Our results showed that the model fit the data well and can thus be used as a theoretical background for burnout and engagement in the school context. Supporting the model (see **Figure 1**), study demands in the last year of comprehensive school were positively related to school burnout in upper secondary education 1 year later, while study resources were positively related to engagement with schoolwork 1 year later. In addition, personal resources, such as self-efficacy in the last year of comprehensive school, were positively related to engagement with schoolwork and negatively to school burnout 1 year later.

In line with the model, engagement with schoolwork and school burnout were both stable during upper secondary education and negatively associated (see **Figure 1**). Furthermore, the cross-lagged paths between engagement with schoolwork and school burnout revealed that school burnout negatively predicted engagement with schoolwork 1 year later, and engagement with schoolwork was positively related to life satisfaction 2 years later, while school burnout was positively related to later depressive symptoms (see also Salmela-Aro et al., 2008c). School burnout was also negatively related to life satisfaction 2 years later. Our results thus indicate that the demands–resources model is a suitable framework for

Figure 1 The demands–resources model in the school context.

explaining student pathways to adjustment and maladjustment in the school context and general adjustment later on. The model includes both an effort-driven energetic process of overtaxing and wearing out in which great demands exhaust energy and lead to burnout and diminished mental health, and a motivational process in which the availability of resources leads to engagement. School burnout mediated the relationship between study demands and mental health outcomes.

Person-Oriented Approach to Engagement and Burnout

Using a person-oriented approach, we have recently examined what kinds of schoolwork engagement and burnout profiles can be identified among high school students (Tuominen-Soini et al., 2011; Tuominen-Sioni and Salmela-Aro, 2014). The results, based on the FinEdu data, showed that students' engagement with school does not necessarily decrease across the school years, but rather that different subgroups of students with varying levels and developmental trends of school engagement can be identified (Upadyaya and Salmela-Aro, in press). In fact, the four-group solution fit the data well. We labeled these groups engaged, engaged–exhausted, cynical, and burnout. The first two were engaged. Those in the engaged group (the largest group with 44% of the students) scored high on schoolwork engagement and relatively low on all the burnout dimensions; in contrast, those in the engaged–exhausted group (28%) scored high on schoolwork engagement but also reported rather high levels of exhaustion and inadequacy. Thus, students can feel engagement and disengagement simultaneously. The other two groups were disengaged: those in the cynical group (14%) scored high, particularly in cynicism, and low in engagement, whereas those in the burned-out group (14%) were characterized by relatively high levels of all three burnout dimensions – exhaustion, cynicism, and inadequacy as a student.

These results show that most students are engaged. As a whole, students who are highly engaged with school typically follow an overall positive youth development trajectory. They produce high academic outcomes, possess a mastery-oriented approach to studying, seldom drop out of school, adapt better to challenging situations, spend their time out of school in constructive activities, and experience overall better well-being (Tuominen-Soini et al., 2011). However, one-third of students evidence clear signs of burnout. We examined these students further during their transition to working life and found that membership in the cynical group increased and that burnout symptoms tended to increase in severity over time in the burnout group (Tuominen-Sioni and Salmela-Aro, 2014).

Developmental Changes in Burnout and Engagement during Educational Transitions

We next analyzed changes in the three components of school burnout – exhaustion, cynicism, feelings of inadequacy – during the transition from comprehensive school to upper secondary education (Salmela-Aro et al., 2008b; Salmela-Aro and Tynkkynen, 2012). The developmental patterns varied by gender and educational track. Although exhaustion increased among boys on the academic track, girls on the academic track reported higher levels of exhaustion than their male peers at all time points. Cynicism decreased among girls on the vocational track but increased among boys on the academic track. Among girls on the academic track and boys on the vocational track, cynicism remained stable. At the end of upper secondary education, cynicism was highest among boys on the academic track. Finally, the level of feelings of inadequacy remained stable among both boys and girls on the vocational track, whereas it increased among both girls and boys on the academic track.

These patterns are consistent with the idea that changes in the fit between students' developmental needs and school settings may change across school transitions differently for various groups of students (Eccles and Roeser, 2009, 2011). During educational transitions, the fit between the student and the school is a crucial factor affecting school engagement and burnout. When inconsistent changes occur in both the adolescent and the school context (Eccles and Roeser, 2009), the stage–environment fit (Eccles and Midgley, 1989) can become impaired. According to the stage–environment fit theory (Eccles and Midgley, 1989), many of the changes associated with educational transitions, in particular in the academic track, are at odds with the changing developmental needs of adolescents (e.g., increased emphasis on grades and competition, decline in adolescents' perception of emotional support from teachers, and sense of belonging in their classrooms). According to the stage–environment fit theory, if schools do not provide developmentally appropriate educational environments for adolescents, they are not offering the kind of social context that will continue to motivate students' interest and, consequently, may result in increasing burnout and decreasing engagement. A negative developmental fit can lead to alienation from school and give rise to cynicism. In contrast when the school context fits well with students' interests, goals, and psychological needs, the result should be continuing high engagement and well-being and low burnout (Eccles and Midgley, 1989; Salmela-Aro et al., 2008b; Salmela-Aro and Tynkkynen, 2012). This scenario may also occur after the transition to higher education or work (Upadyaya and Salmela-Aro, in press). The results from tFinEdu study suggest that, while the level of overall engagement might be low during postcomprehensive education, it may increase after the transition to higher education or work (Upadyaya and Salmela-Aro, in press) because the new study or work environment may provide a better person–environment fit for some young adults (Eccles and Midgley, 1989; Eccles and Roeser, 2009).

Girls often exhibit higher levels of behavioral, emotional, and overall school engagement than boys (Salmela-Aro and Upadyaya, 2012; Wang and Eccles, 2012), which may be related to girls' tendency to perform better at school (Pomerantz et al., 2002) and to attribute greater importance to academic achievement than boys, as well as a better fit between the students' needs and the school culture for girls than for boys (Berndt and Miller, 1990). Consistent with these hypotheses, boys are more likely than girls to experience rapid

decreases in engagement and to follow unstable school engagement trajectories, often leading to school dropout (Li and Lerner, 2011).

For both boys and girls, high levels of secondary school engagement predict higher education and better job possibilities (Upadyaya and Salmela-Aro, in press; Vasalampi et al., 2009), as well as life satisfaction (Salmela-Aro and Tuominen-Soini) and well-being (Salmela-Aro and Upadyaya, 2014) later in life. In contrast, burnout predicts more gap years and difficulties in negotiating the transition to working life and later education (Vasalampi et al., 2009). Recent studies have also revealed that during involuntary gap years after high school, burnout decreased and engagement increased (Parker et al., submitted for publication).

School Burnout and Engagement in Varying Social Contexts

Students' social contexts (parents, peers, teachers, and the school environment) also predict school-related engagement and burnout (see reviews by Upadyaya and Salmela-Aro, 2013; see also Finn and Rock, 1997; Finn and Voelkl, 1993; Eccles and Roeser, 2009, 2011). Supportive relationships with parents promote students' school engagement: parental involvement and support positively predict students' school engagement (Upadyaya and Salmela-Aro, in press; Wang and Eccles, 2012). When students have a good relationship with their parents, they also seem more likely to complete a successful transition to higher education or working life (Upadyaya and Salmela-Aro, in press; Vasalampi et al., 2009). A good, supportive relationship with parents is an important resource for school engagement and continued educational and career success (Upadyaya and Salmela-Aro, in press; Wang and Eccles, 2012). However, the FinEdu results also revealed that burnout is shared in the family (Salmela-Aro et al., 2011). In particular, levels of mothers' work burnout and daughters' school burnout are correlated as are fathers' work burnout and sons' school burnout.

School engagement and burnout can also be shared among students in the same peer group (Kiuru et al., 2008, 2009). In the FinEdu data, both the level of and changes in school burnout were shared in a peer group (Kiuru et al., 2008). Moreover, a selection influence was found for school engagement. In addition, high levels of school engagement were shared especially among tight peer groups of girls, probably because girls in highly cohesive peer groups experience a higher sense of belonging, which is related to school engagement (Kiuru et al., 2009).

But who influences whom? Using FinEdu data, we found that maternal affection moderates the influence that higher-burnout friends exert over the subsequent schoolwork engagement of their lower-burnout friends (Marion et al., 2014) such that the schoolwork engagement of the friend reporting higher levels of school burnout predicts a decline in the schoolwork engagement of the friend reporting lower school burnout only if the latter reported lower than average maternal affection. These results suggest that warm family relationships can buffer against negative peer influences.

In addition, teachers can play a role in school burnout and engagement (Pyhältö et al., 2011; Salmela-Aro et al., 2008a). Although the effects were small, students' burnout is predicted by higher levels of haste and lower levels of general atmosphere. In contrast, the fairer and more encouraging the teachers in high school are perceived to be, and the more supporting adults are available, the less burnout is reported by the students (Salmela-Aro et al., 2008a). Thus, during adolescence, teacher support and fairness can help support students' sense of engagement (Salmela-Aro et al., 2008a), as can perceived support for student autonomy and feelings of relatedness (Deci et al., 1991).

Intervention to Promote Engagement and Prevent Burnout

Although school transitions include several risk factors for student engagement (Roeser et al., 1999), they also offer opportunities for change and possible interventions. One possibility is to boost students' transition efficacy and related resources and provide them with information on the opportunities and challenges of further education and career opportunities prior to their transition to vocational studies, higher education, or work. Such preparedness (Salmela-Aro et al., 2012) would enhance students' subsequent engagement and the value they attach to educational goals, and help them in adjusting to the upcoming educational transitions (Vuori et al., 2008).

Recently, an intervention titled Towards Working Life was implemented at the end of comprehensive school in Finland with the aim of promoting student preparedness for the impending educational transition (Vuori et al., 2008). It was assumed that transition preparedness would subsequently increase school engagement and decrease burnout. Transition preparedness has two components: promoting transition-related resources, such as self-efficacy, and increasing preparedness for possible setbacks and challenges during the transition. The results of the randomized trial documented the effectiveness of this intervention for increasing students' transition preparedness. In addition, increased transition preparedness predicted decreasing levels of students' school burnout later in upper secondary school (Salmela-Aro et al., 2010). Key educational transition periods seem to be windows of opportunity for changes in burnout and engagement. These are also ideal places to carry out interventions to boost transition preparedness and school engagement.

Conclusion

In this article, processes associated with both schoolwork engagement and school burnout were presented in the context of the school demands–resources model. According to this demands–resources model, high school demands lead to burnout, whereas high personal and school resources lead to engagement. In turn, engagement can lead later on to overall satisfaction with life, whereas burnout can lead to later depressive symptoms. Moreover, school burnout predicts decreases in engagement later on rather than vice versa. Second, taking a person-oriented approach, four burnout–engagement profiles were presented in the high school context. Although most students were engaged, one-third

suffered from burnout. In addition, about one-third experienced high engagement and exhaustion at the same time. This combination can be demanding later on during transition from high school to further studies. Third, attention was paid to the role of educational transitions in gendered school burnout trajectories. Girls seem to suffer more from burnout, but both girls and boys on the academic track reported an increase in feelings of inadequacy. School burnout and engagement were also considered in the social context. The role of peers, parents, and teachers all seem to be crucial. Finally, the results of a recent intervention program aiming at increased transition preparedness for possible setbacks related to educational career were described. It was found that transition preparedness promoted school engagement and decreased burnout in students' subsequent educational careers.

These findings can be approached in the context of the 4C (channeling, choice, coregulation, compensation) life-span model of motivation (Salmela-Aro, 2009). In line with this model (Salmela-Aro, 2009; Dietrich et al., 2012), various environmental characteristics, such as the transition to school and to work, channel students' engagement and burnout. However, students coregulate their engagement and burnout in reciprocal relationships with parents, peers, and teachers. The changing fit between students' developmental needs and school settings (Eccles and Roeser, 2009) may be reflected in changes in students' engagement. However, a crucial role in engagement is played by young people's own choices, agency, and related personal resources. Finally, young people can be helped to reduce problems of engagement and burnout (compensate): boosting their transition preparedness played a key role during these major educational transitions by promoting engagement and preventing burnout later on. Perseverance in the face of obstacles seems to lead to advantageous outcomes such as engagement.

Future Directions

There are several issues that should be taken into account in future research on school burnout and engagement. First, students' burnout and engagement need to be examined in different academic domains, such as STEM (science, technology, engineering, and math). Some students might feel highly engaged with math and sciences but lack engagement with the arts and languages. This would help to understand the processes through which engagement and burnout develop in school. Second, more research using experience sampling methods is needed to reveal burnout and engagement processes during the school day. What really engages students and when are students most burned out? Do students feel more engagement when doing sports than academic subjects? Daily and weekly fluctuations in burnout and engagement, and situational and contextual factors affecting burnout and engagement might be then revealed. Moreover, this article is based on data collected in Finland, and as school systems and contexts may vary greatly between countries more research is needed in other countries and school contexts. In addition, this article focused on adolescents, and thus engagement and burnout processes during elementary and middle school should also be examined. Finally, new challenges for schools, such as segregation in neighborhoods and increasing immigration, need to be addressed in the context of burnout and engagement.

School Business Management

Abstract

The role of school business managers (SBMs) in the English state school system has grown exponentially over the past decade. The roots of the SBM can be traced to its forerunner, the school bursar, and private schools where the role had been long established before a period of large-scale educational reform provided the catalyst for its growth within the state school sector. In 2002, a national government initiative launched the inaugural program of training and certification for school bursars in a bid to dramatically increase their numbers in schools in England. Since then the role has evolved into the SBM, a post that encompasses a range of responsibilities far greater in scope and diversity than those of their bursarial predecessors. Research evidence suggests that while SBMs are making a positive impact in English schools there remain cultural barriers from some educational stakeholders who have yet to fully embrace the profession and its potential. Looking forward, indications suggest that SBMs will have a central role to play in the modern day educational setting.

Introduction

This article outlines the growth of school business management in the English state school system. It begins with the origins of the bursar within the private school sector before discussing the gradual introduction of the role into state schools, a process fueled significantly by the educational reforms of the late 1980s. The chapter then considers how a large-scale government strategy in 2002 initiated the evolution of the school business manager (SBM) role, a role that would become increasingly professionalized over the following decade. International comparisons are drawn followed by some of the recent research evidence on the impact being made by SBMs in England. The chapter concludes with some thoughts on the future of the profession.

School Business Management: A Brief History

The roots of school business management in the English state school system can be traced back to bursarship, a profession traditionally associated with the independent school sector. The bursar would have been predominantly responsible for the financial management of a school, college, or university with typical candidates being exmilitary personnel who often found their personal management and organizational skills suitable for the role (Kerry, 2001). One of the more illustrious incumbents of this profession was the economist John Maynard Keynes (1883–1946) who was bursar at King's College, Cambridge between 1924 and 1944, a time during which he 'amassed a considerable personal fortune from the financial markets' and 'greatly improved the college's financial position' (BBC, 2012). In a more informative account of the specifics of the traditional bursar, O'Sullivan et al. (2000) cite the biography of Robert Somerville, both master and bursar at the Harrow School for 33 years between 1887 and 1920, whose responsibilities included relieving teachers of their nonteaching duties, advising on school development plans, and dealing with contractors and estates.

Such insights illustrate the long and distinguished history of bursarship (the roll of bursars at King's College is traceable to the 1400s) and what is also interesting about this account are the parallels between Robert Somerville's role and those of his modern day successor, the SBM. Perhaps because of their predisposition to employment within the independent school sector, such references to bursars are rare within historical research literature.

Within the state school sector, it was not until the early 1980s that scholarly attention turned toward those members of the school workforce not directly involved with teaching and learning. Colin Riches conducted some of the earliest academic research studies on what he termed 'nonteaching staff,' an umbrella term he used to categorize all school staff who were not qualified teachers such as administrative and clerical assistants, caretakers and cleaners, grounds staff and gardeners, and school meals staff (Riches, 1981). Within his research he alludes to the fact that nonteaching staff are often equivalent in number to their teaching counterparts while indicating the implications of this evolving group of school support staff for the head teacher tasked with:

> managing a workforce which is to some extent not his own, and yet these staff are often/sometime in positions of influence in the school, e.g. the controlling caretaker and the "gatekeeper" secretary.
> Riches, 1982, p. 154

It is notable that in modern day schools, the management and coordination of this 'workforce' is often the responsibility of the SBM whereby Riches' observations were perhaps early signs of the growing nonteaching obligations of the head teacher. Around this time, the Local Education Authority (LEA) for London undertook some research exploring the implications of increasing workloads for teachers with a view to improving achievement in schools. While nonteaching staff were not the primary focus of this research, one of the recommendations from the final report suggested an increase in provision for administrative assistants in schools to relieve deputy head teachers of their clerical duties (thus allowing them more time in the classroom) (The Hargreaves Report, ILEA, 1984). Though sporadic, these glimpses of nonteaching staff highlight their developing

profile, which, by the end of the decade, was set to increase significantly.

Bursars in State Schools

The educational reforms of the late 1980s, in particular the Education Act (HMSO, 1988), ushered in a new era of autonomy for schools handing them greater control over their finances and strategic planning. One of the key measures of this act was a system of site-based management known as Local Management of Schools (LMS) which gave head teachers and governing bodies more autonomy over their school's budget (the assumption being that increased decision making at school management level would bring about improved educational outcomes for pupils; Levačić, 1998). Beforehand, schools were only responsible for the area of the budget relating to teaching materials (e.g., books and stationery) with the LEA held accountable for staff employment and buildings/premises maintenance. LMS gave schools responsibility for the majority of their budgets, which, in turn had implications for the role of the head teacher:

> LMS dramatically changed the role of the head teacher from educationalist to institutional manager. S/he now had to learn about recruitment and selection procedures, employment law, buildings maintenance etc.
>
> Gillard, 2007

This facilitated an emergence of specified bursarial roles, previously not seen or required, within the state school sector to accommodate this new level of responsibility. One head teacher at this time reports on the recruitment of a bursar in his secondary school following the onset of LMS and the new financial management responsibilities it would bring:

> the need for informed and inspired leadership is greater than ever but so is the threat that time for leadership will be swamped by the need for good management. Hence the need for a bursar who can remove the clutter of LMS from the academic and pastoral leadership in the school.
>
> Gittins, 1989, p. 169

From an early stage there was an awareness of the advantages of employing a bursar. Mortimore et al. (1994) underline the benefits of the role such as the streamlining of administrative and financial operations within a school and the relieving of heads and deputies of nonteaching duties. However, they also point to the "the disparity between the new post and the traditional secretary" and "the considerable workload, post-LMS, of the new post-holder" (p. 28). Knight (1993) goes further, suggesting possible tensions should nonteaching staff such as bursars become too involved in decisions concerning pupil education and that a newly appointed bursar "needs a thorough induction into this strange new world" (p. 49).

As the profile of school bursars was slowly developing so was their role evolving to meet the needs of a school system in flux. For instance, Szemeremyi (1991) discusses the possibility of schools generating their own income via fund raising and grant applications. He advises that "appeals to firms will have to be couched in more business-like terms" (p. 113) and composed as "methodologically prepared business plans" (p. 114) before concluding that the appointment of a "facilities development manager whose salary is paid from the extra income generated" (p. 114) would perhaps be the most sensible option. Without specifically mentioning bursars, the remit he describes is typical of a modern day SBM who is expected to have the requisite business acumen to raise money and to justify at least a portion of their salary from the income they generate.

The majority of these early references to bursars in state education focused on the secondary school sector which is unsurprising, given that they tend to be larger schools with wider bursarial needs (with regard to premises, buildings, and financial management) and bigger budgets to justify the salary of a bursar. Yet, there is evidence from this time that primary school head teachers were beginning to feel the strain of an ever increasing administrative burden coupled with their curriculum and leadership duties (Webb and Vulliamy, 1996) and that this was dampening the aspirations for headship for those leaders further down the career ladder such as those of deputy heads (Webb and Vulliamy, 1995). However, for most primary schools a bursar remained an unaffordable luxury (Knight, 1993) although there were suggestions that clusters of smaller schools might pool their finances to share a bursar as a way around this problem (Harrison and Gill, 1992).

Throughout the 1990s the role of the bursar continued to develop in tandem with the leadership and management requirements in schools. The following extract is taken from an interview with a head teacher speculating how the role of the bursar in her school might need to evolve to release her deputy head from an increasingly onerous management burden:

> We may need to change the role of the bursar. We might need someone to take on those activities and also to take away the detailed financial responsibilities carried by one of the deputies who, after all, should have an educational function … We have got to be aware, because of the new management functions we have had to take on, that senior staff do not lose sight of the fact that their main managerial functions should focus on the education of the pupils.
>
> Head teacher in Ribbins and Marland, 1994, p. 48

This gives an insight into the way schools were beginning to adapt and reorganize their staffing structures, to accommodate this new level of independence from the LEA, and the opportunities this would provide for bursars. However, it is also an indicator of the potential pitfalls of these changes in terms of the senior school leaders' workload priorities:

> If I think back, for example, to the start of LMS none of us was trained in managing budgets. None of us had come into teaching expecting that would be part of any role we would have to play as senior managers.
>
> Ribbins and Marland, 1994, p. 48

There were suggestions from academics that the shifting educational landscape was changing the culture of headship considerably so that the role was becoming complex and variable than ever before (Hellawell, 1991; Evetts, 1991; Weindling, 1992) and that the head teacher was being transformed into a kind of corporate manager (Evetts, 1994).

The stage seemed set for bursars to enter and relinquish head teachers and senior leaders of their nonteaching responsibilities though their steady influx into schools was not an entirely smooth transition. In a study of 18 secondary schools, exploring their use of resourcing post LMS, Thomas and Martin (1996) found that the majority had created a new bursarial position to accommodate the changes resulting from LMS although none were appointed at a grade comparable to the deputy head teachers and perceived, as they were, 'to be in a service and support role' (p. 57). They also discovered tension in one school whose governing body was concerned about the level of influence a bursar might develop given the budgetary information they had at their disposal. In the first book to focus entirely on bursarship, O'Sullivan et al. (2000) draw on their research with bursars in state schools to highlight the growing profile of the role and its increasing significance in the operation of the school. They describe the bursar "as a 'fixer' in a turbulent sea of problems and issues" from which they emerge "as a well-known, respected, and approachable colleague with considerable technical and managerial expertise" (p. 43). However, they also point to an "underlying tension and a sense of inferiority" whereby "teachers were regarded as finding it very difficult to come to terms with the idea of bursars as anything other than office clerks" (p. 68).

While it is not entirely straightforward trying to coherently piece together these rather patchy references to bursars there are some recurrent and consistent themes. Firstly, that the educational reforms of the late 1980s were having a significant impact on the amount and type of work that head teachers and senior school leaders were responsible for with schools adapting their staffing structures to cope with this additional workload. Secondly, although these new structures appeared to be alleviating the financial and administrative burden from teachers, allowing them to spend more time on the educational agenda, there were also inherent cultural tensions arising from these organizational changes. These themes would remain ever more relevant heading into the new millennium.

The Evolution of the SBM

In 2001, responding to a perceived crisis in the recruitment and retention of teachers due to heavy workloads, the Department for Education and Skills (DfES, as was), appointed PricewaterhouseCoopers to conduct a large-scale research study into teachers' and head teachers' workloads. The findings from the *Teacher Workload Study* (PricewaterhouseCoopers, 2001) were largely confirmatory highlighting increasingly onerous workloads for teachers and head teachers (compared to managers and professionals in other vocations) specifically the amount of administrative work and the lack of bursarial support, unrelated to teaching and learning, which could be carried out by support staff. Smithers and Robinson (2003) supported these findings in questioning over 1000 departing teachers across all phases of schools to reveal that almost 45% blamed a heavy workload as their main reason for leaving. According to Gunter and Butt (2005) an aging teaching population coupled with significant numbers of newly qualified teachers leaving the profession within just 3 years had led to "a generation of teachers in school who will retire in the next decade" and whose "replacements are not staying the pace" (p. 1). The government's response was an upheaval in the structure and design of the school workforce to facilitate support staff (such as secretaries, technicians, teaching assistants, and bursars) taking on more of the work traditionally done by teachers. *Raising standards and tackling workload: a national agreement* (DfES, 2003b) was the beginning of a period of what would come to be known as *workforce remodeling* in which support staff roles in schools were increased and developed to accommodate more responsibility.

Bursars had a significant role to play in this restructuring process, and in 2001 Estelle Morris, the then Secretary of State for Education, announced that the government would fund training for 1000 new school bursars within 5 years. The previous year the New Labor government had signaled their intent to raise the profile of school leadership and leadership preparation by establishing the National College for School Leadership (NCSL) with an aim of putting in place the world's largest leadership development program by 2004 (NCSL, 2001). It was the NCSL who the government commissioned to develop a national program of training for bursars in a bid to facilitate recruitment and professionalize the role while offering them a clear and structured career path. In 2003, following some pilot work, the Bursar Development Program (BDP) was rolled out nationally with an entry level Certificate of School Business Management (CSBM) covering the basic skills for school finance and resource management. This following year the more advanced Diploma of School Business Management (DSBM) was initiated and it was also around this time that the title of School Business Manager (SBM) was introduced to more accurately reflect the expanding nature of a role which was no longer predominantly concerned with school finances, as indicated by the more traditional title of 'bursar' (Southworth, 2010). The renamed School Business Manager Development Programme (SBMDP) would continue to expand adding an Advanced Diploma of School Business Management (ADSBM) in 2008 and a School Business Director (SBD) program in 2010 along with an SBM competency framework, developed with the National Association of School Business Managers (NASBM) illustrating the six main areas of this continuously evolving role.

School Business Management: A Growing Profession

With the establishment of a national training program and accompanying competency framework, SBMs (as they were now more commonly referred to) were becoming increasingly qualified and professionalized (Coulbeck, 2006). Furthermore, the nature of school leadership was changing to become more dispersed among senior staff members (Hartley, 2007; Gronn, 2003) and, as such, links were beginning to be forged between SBMs and the role they might play in the leadership and management of schools.

For example, drawing on participant evaluation and case study data from early cohorts of the CSBM, Moorcroft and Summerson (2006) found instances where head teachers had relinquished elements of operational control of the school to their SBMs and recruited them onto their Senior Management/Leadership Teams. In such cases the status of the SBM in their school was markedly improved as were the teaching staff attitudes toward the role. Conversely, they also found examples of SBMs facing barriers to change particularly where senior teaching colleagues were apprehensive about nonteaching staff taking on leadership roles. The authors suggest that this may be due to them having little understanding of the merits of the SBM role coupled with a lack of trust in their nonteaching counterparts. Similarly, Coulbeck (2006), working with SBMs on the C/DSBM courses, reports on firsthand accounts from participants to describe the positive impact they are having on the leadership, management, and administration of schools. Further, she argues that the growing number of professional qualifications for SBMs is a clear sign that school business management is emerging as a new profession. However, she also highlights a number of challenges faced by SBMs in establishing their professional identities including a lack of acknowledgment from teaching staff and governors; skepticism about the value of their professional training and; a reluctance of senior members of staff to recognize the candidacy of the SBM for membership of the SLT. These findings are akin to those from Aldridge (2008) who conducted cross-sectional surveys with SBMs on the CSBM to explore their roles in the evolving nature of school leadership; while his results indicated "distributed leadership teams, incorporating SBMs/Bursars, across many schools, their uptake is patchy with head teachers, governors and senior leadership members not always being aware of all the potential benefits" (p. 1).

The evidence presented here indicates the potential of SBMs to play an increasingly active role in school leadership set against the wider cultural barriers that accompany skepticism toward staff from nonteaching backgrounds taking on senior leadership roles in school.

Such notions are supported by Woods (2009) who, based on her own interviews with SBMs, draws attention to the growth of school business management, the link between the SBM role and distributed school leadership, and the tensions inherent in this relationship. She suggests that ongoing educational reforms have significantly altered the organization and purpose of schools leading to schools offering child welfare services far beyond the capacity of the traditional educational model (e.g., *Every Child Matters*, DfES, 2003a). Furthermore, schools are increasingly working in partnership with other schools (i.e., as federations and trusts) and morphing into larger, more complex structures (i.e., academy chains, learning communities) which "imply an increased role for SBMs in assisting their teaching colleagues in managing their schools' complex agendas in future" (p. 89). While acknowledging the progress and development of school business management Woods believes there remains a tension between teachers feeling their profession threatened by nonteaching staff and SBMs frustrated at being unable to realize their professional leadership training and potential within the school. She proposes that a clearer understanding from both groups of their mutual objective – of improving the educational and welfare outcomes of pupils – may help to harmonize the relationship in the future:

> Through fostering a shared understanding of how their contributions are different, but nonetheless essential, given the way schools now operate, potential for greater interdependence between teaching and administrative staff may result over the longer term.
>
> Woods, 2009, p. 90

Despite the cultural barriers faced by SBMs, the evidence presented here illustrates how far the role has progressed and developed since its earlier incarnation, the bursar, which first emerged in the state school system back in the late 1980s.

SBMs: An International Perspective

Internationally, there are signs of a similar push to raise the profile and develop the role of nonteaching school staff members with business, finance, administration, and human resource acumen as the requirement for roles incorporating these skills increases in educational settings across the globe.

In South Africa, a pilot group of 107 graduates became the first SBMs in their country to qualify for the inaugural Certificate for School Business Administrators (CSBA). This was the result of over 5 years of development work between the NCSL, Manchester Metropolitan University (MMU), and the Western Cape Education Department in which the NCSL provided course materials from its own CSBM to inform the design of this new accreditation. Covering areas such as financial management, human resources, risk assessment, facilities management, ICT systems, and the wider school environment the CSBA has, for the first time, given South African SBMs the opportunity to become qualified professionals (NCSL, 2010; Education Update, 2012).

As a profession, school business management is more established in Australia which has a number of professional organizations supporting SBMs (e.g., Association of Business Managers in Victorian State Schools (www.education.vic.gov.au), Schools Business Managers' Association Queensland Inc. (http://www.sbmaq.com.au)) although provision varies across the country with some regions yet to embrace the role. For example, primary and secondary school principals in New South Wales recently proposed the introduction of business managers into their schools to help alleviate their nonteaching responsibilities thus allowing them greater focus on the teaching and learning agenda. However, differences between states in regulations surrounding school staffing budget allocations mean that schools in Victoria for example have more flexibility in their workforce recruitment. As such, SBMs are a more familiar sight in Victorian schools (Newman, 2009). Research has also highlighted the range of responsibilities encompassed by SBMs across Australia including finance, facilities, and resource management; governance and strategic planning; human resources; accountability and legal oversight. Additionally, they often manage support staff, supervise extra-curricular provision (e.g., breakfast clubs, school trips), and are even

involved in making time tables and in teacher/classroom allocation (Starr, 2012).

In the United States, school business management is a well-established profession (the Association of School Business Officials International (www.asbointl.org) was formed in 1910) and forms an integral part of their education system. Unlike the United Kingdom and other countries discussed, School Business Officials (SBOs) operate at the district level in an overarching role often working with several schools and principals simultaneously although many of their areas of responsibility would be familiar to SBMs in other parts of the world. These include budgeting, purchasing, financial management, maintenance, human resources, ICT, pupil transportation and security, catering, and health care (ASBO, 2012). As business management is a district responsibility, school principals tend to be much more focused on classroom instruction and are able to spend a lot of their time working with students and teachers.

SBMs: Current Research

Recent large-scale studies have offered further illustrations as to the impact SBMs are having in schools. For instance, the NCSL funded a national program of interschool partnerships where clusters of schools were funded to develop bespoke models of shared, effective business management expertise. An evaluation of this program from researchers at the University of Manchester evidenced a variety of ways in which SBMs were positively impacting on the schools in which they were working. For instance, their experience in site and project management was relieving senior teaching colleagues of these duties thus saving them time and effort; they were taking advantage of economies of scale to secure best value from suppliers for the schools in their cluster; taking on responsibility for school policies and procedures (e.g., health and safety) thus relinquishing teaching staff from these obligations; utilizing their knowledge of human resources knowledge to aid the professional development of , often, large numbers of support staff employed across their clusters; and networking with other SBMs, outside agencies and the wider community to benefit their school(s). Their impact had also led to improvements in both the head teacher job satisfaction and pupil outcomes (University of Manchester, 2010). Moreover, evidence also emerged from this large-scale program of significant financial benefits associated with increased savings and higher income generation as a result of schools having access to a suitably qualified SBM (PricewaterhouseCoopers, 2010; Oakleigh, 2010).

Drawing on the outcomes of this research, Woods et al. (2013) highlight the benefits of school to school business management partnerships, with a suitable qualified SBM (or a range of staff members performing elements of the SBM function) as the fulcrum of such arrangements, as a viable alternative to school collaboration based on educational expertise. Similarly, Mertkan (2011) refers to the SBM role as a potential vehicle for closer collaboration and partnerships between schools and businesses while Southworth (2010) underlines how SBMs have moved on from dealing purely with school finances and now have a "portfolio of responsibilities and skills that supplement and complement those of other school leaders" (p. 3). He believes that this upsurge in the training and deployment of the thousands of new SBMs across schools in England over the past decade is a "revolution in education" (p. 3) to rival the rise in classroom teaching assistants or the escalation of school leaders operating beyond their own sites to support and lead other settings. Woods et al. (2012) explored the impact of SBMs on primary head teacher succession. Their findings indicate a number of ways in which having a suitably qualified SBM at that post could impact on school leaders at different stages of their careers and also aid leadership succession. These included making the head teacher role more attractive for aspiring leaders; easing the transition period from new or acting to full-fledged head teacher; assisting the head teacher in a challenging or crisis situation (e.g., a poor inspection); and helping retain experienced head teachers who were thinking of early retirement. Other research has uncovered evidence of SBMs rising to influential strategic leadership positions in their schools or being appointed as part of an improvement plan to turn around a failing school (Armstrong, 2012).

Looking Forward

Following over two decades of educational reform, instigated largely by the LMS initiative, increased demands on schools and school leaders have coincided with a restructuring of education to adopt more business like approaches. This has generated significant challenges to educational leaders whose workload has expanded in both volume and diversity with a range of pressures, in addition to the teaching and learning agenda (e.g., financial, legal, and technical) which have become impossible to deal with independently (PricewaterhouseCoopers, 2007). As the system has been rearranged, this has created new spaces that have been populated by nonteaching professionals with different skill sets to support and compliment the work of educational leaders. The election of a new coalition government in the United Kingdom in 2010 has intensified further the pace and intensity of educational reform. However, while previous governments had tinkered with deregulation and market forces, the new government has freed up the system to a previously unseen extent (Hatcher and Jones, 2011). Initiatives such as the academies programs have removed significant numbers of schools from the services of their Local Authorities (LA; essentially rendering this middle tier of government obsolete) and the introduction of Free Schools into the system has added a further dimension to this shifting educational landscape (Gunter, 2011).

For SBMs such changes have meant an increased workload as schools converting to academy status must find alternatives to the services their LA once supplied. Furthermore, the regulations surrounding the requirement for academies to employ a qualified accountant were recently relaxed thus creating opportunities for SBMs to take on the financial management of schools without the need for accountancy qualifications. As schools and educational settings moved forward and are increasingly reliant upon themselves for funds, services, and resources in a competitive business-like environment there is

an expectation that the SBM role will become a necessary requirement (DfE, 2010). It would, therefore, seem that SBMs are set to play an increasingly vital role in the modern state school system in England.

School Choice

Mark Berends, Center for Research on Educational Opportunity (CREO), Research Center on Educational Policy (RCEP), University of Notre Dame, Notre Dame, IN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

School choice is one of the several educational reforms being implemented in the United States to address persistent inequalities among students and the communities in which they live. Yet, school choice takes on a variety of forms, whether that be private or religious schools, charter public schools, choice scholarships or voucher programs, educational tax credits, or homeschooling. This article examines the research on these various aspects of choice in the United States, placing the research in broader theoretical frameworks, and directing attention to future research to inform the conditions under which school choice is effective or not.

Introduction to School Choice

Although there are a myriad of school reforms that have been proposed and implemented over the past several decades, one that receives a great deal of attention is school choice, which refers to a variety of programs providing families the option to choose the school their children attend. School choice options may include neighborhood public schools, private schools, magnet schools, charter public schools, vouchers or tuition tax credits, homeschooling, inter- and intradistrict choice plans, and supplemental educational services (Berends et al., 2009; Berends, 2014). The public may not understand the meaning of the many forms of school choice, but the idea that parents should have some choice in the education of their children is deeply ingrained in the U.S. culture as well as many other countries (Berends et al., 2009, 2011).

In this article, I will place the research on school choice within a theoretical framework, drawing on market theory and institutional theory. I then will discuss the research and findings on the various aspects of school choice in the United States and other countries, focusing on Catholic schools, charter public schools, choice scholarships or voucher programs, education tax credits, and homeschooling. After highlighting the findings from the more recent rigorous studies on school choice effects, I will point the direction toward research that draws on the social organization of schooling as a way to further research in this area. In this perspective, researchers focus their attention inside schools – examining the relationships between teachers and students as well as the other social relationships among parents, peers, and administrators – to understand how the organization of schools influences the learning opportunities and schooling processes within schools (Bidwell and Kasarda, 1980). Summarizing the importance of this perspective when examining school choice, Schneider (2003: 212) writes

> Studies of school choice have also not yet overcome the inadequacies we find in studies of the social organization of public schools. One reason may be that the pressure to link school choice with gains in student achievement has placed issues of selection bias and test score differences at the forefront, thus overshadowing serious efforts to examine qualitative differences in the learning opportunities experienced in choice versus other types of school settings.

Evolving Aspects of School Choice in the United States

Federal policies have provided support for school choice over the past decade. The No Child Left Behind Act (NCLB) promoted choice for families if schools failed to make adequate progress over time. As part of the more recent $4.0 billion Race to the Top program, the Obama administration has called for an expansion of charter schools, awarding funding to states for school reforms related to adopting standards and assessments for college and workplace readiness, recruiting effective teachers and principals, building data systems to measure student progress and inform educators, turning around low-achieving schools, and expanding the number of charter schools.

Some choice options that have grown significantly in the past two decades is parents sending their children to charter schools – schools that are publicly funded but run under a charter by parents, educators, community groups, universities, or private organizations to encourage school autonomy and innovation. As the fastest growing area of school choice, there are currently over 6000 charter schools serving more than 2.2 million children across the United States or 4.5% of the K-12 student population (National Alliance for Public Charter Schools, 2014; U.S. Department of Education, 2012).

Another growing area of school choice is scholarships or vouchers and tuition tax credits. *Vouchers* or *choice scholarships* provide parents the option of sending their children to the school of their choice, whether public or private, religious or nonreligious schools. With public funds usually spent by the district, vouchers are allocated to families for tuition payments, in part or perhaps in full. *Education tax credits* are provided to either corporations, individual families, or both. At the *corporate* level, businesses receive a state tax credit for making donations to nonprofit organizations called Scholarship Granting Organizations (SGOs), which use the donated money to fund private school scholarships for students. Anyone can start an SGO, and some establish certain income criteria for students to be eligible for scholarships. At the *individual* level, parents can receive a tax credit or tax deduction from state income taxes for approved educational expenses, which typically include private school tuition, books, supplies,

computers, tutors, and transportation. Some programs have income restrictions for family eligibility or set the amount families can claim on their taxes.

The number of students participating in different voucher programs across the nation has increased significantly in the last decade – even though the total number of students receiving vouchers is a small fraction of the total number of students in the United States (see Berends, 2014). (For a description of these voucher programs and the urban locales in which they are being implemented, see http://www.edchoice.org/School-Choice/School-Choice-rograms.aspx.)

For example, one of the more well-known voucher programs is the Milwaukee Parental Choice Program, which started in 1990; the program provides vouchers (capped at $6442) to families earning up to 300% of the federal poverty level (about $69 000 for a family of four in 2012). In 1991, 337 Milwaukee students received a voucher; in 2013, 24 027 students received one. Another voucher program of note is Florida's John M. McKay Scholarships for Students with Disabilities, providing vouchers to public school students with disabilities to attend private or other public schools. Starting in 2000, the program served 23 011 students in 2013. A more recent voucher program is Indiana's Choice Scholarship Program, which allows student in low- and middle-income families to receive vouchers to attend private schools. Beginning in 2011 with 3919 students, the number of participating students increased to 20 047 students in 2013–14, making the program one of the largest in the United States.

Another area of growth in school choice is the home-schooling – the education of students at home, typically by a parent. The number of homeschooled students in the United States has increased from 850 000 in 1999 to over 1.5 million in 2007. In 2007, about 2.9% of the K-12 student population was homeschooled (U.S. Department of Education, 2012).

Despite the growth in charter schools, voucher programs, education tax credits, and homeschooling, other areas of school choice are declining. Nationally representative data reveal that between 1995–96 and 2009–10, there has been a general decline of students in pre-K-12 private schools in the United States (Aud et al., 2013). This overall trend masks some shifts in the private sector between 1996 and 2010. For example, there has been a decrease in the number of students attending Catholic schools and increases in the number of students attending unaffiliated private schools – schools that have a more general religious orientation or purpose, not identifying with a specific religion or faith (Aud et al., 2013).

The Catholic school sector in particular is undergoing significant changes. One important change is due to severe financial crises, resulting in many schools either closing or consolidating with other Catholic schools. At the same time, increasing operational expenses in conjunction with dire economic conditions make it difficult for many schools to survive. Between 2000 and 2011, 1755 Catholic schools either closed or consolidated, and there has been a Catholic school enrollment decline of over 22% (McDonald and Schultz, 2011; see also Uecker, 2008). Because of the changing demographics surrounding the Catholic sector in the United States, continued research on Catholic school effects is worthwhile to examine changes over time.

Theoretical Perspectives on School Choice

As school choice programs continue to expand, additional research will likely increase our understanding of the impact of choice options on families and students. As this research unfolds, it is important to keep in mind different theoretical frameworks that guide the research. Specifically, there are two competing theories about the possible impact of choice schools on teaching and learning and in school organizational conditions – market theory and institutional theory (Berends et al., 2010). Many reformers maintain that market style mechanisms of consumer choice and competition between autonomous schools will encourage diverse and innovative approaches to school organization, teaching, and learning (e.g., Chubb and Moe, 1990; Walberg, 2011; Walberg and Bast, 2003). The assumption is that as school choice undercuts bureaucratic political control of public education, it provides educators in schools of choice the opportunity and motivation to experiment with new organizational and instructional strategies to improve student achievement.

Proponents of choice argue that providing this freedom not only diversifies educational opportunities but also creates incentives for the improvement of traditional public schooling through increased market competition for services (Chubb and Moe, 1990; Friedman, 1962). In large part, this argument is about how market competition decreases the amount and influence of historical bureaucratic structures to increase the opportunities for parents and school staff to better relate to address parents' demands.

Some hold that privatization and school choice can bring about 'creative destruction,' borrowing from Joseph Schumpeter, who in the 1940s argued that entrepreneurs relied on radically new technologies – whether more effective, more efficient, or both – to promote economic progress and replace older technologies (Walberg, 2011; Schumpeter, 1942). As the theory goes, such privatization and increased choice will lead to better outcomes, lower costs, and greater satisfaction of employees, parents, and students. According to Walberg (2011: 73), "market-based consumer-driven school choice seems the best hope for creative destruction of new technologies, the expansion of choice, competition, and diversity for substantial, sustained achievement improvement." Chubb and Moe (1990: 217) hold a similar position, calling choice a "revolutionary reform that introduces a new system of public education."

Critics of the market model, however, raise questions about the empirical validity of its key assumptions about parent-consumers (demand-side), schools (supply-side), and the products that a market in education would generate (Finnegan, 2007; Henig, 1999). From such criticism comes an alternative theory about the consequences of school choice: institutional theory. Stemming from broader organizational analysis, this *new institutionalism*, developed by John Meyer and colleagues over several decades (Meyer, 1977; Meyer and Rowan, 1977, 1978; Powell and DiMaggio, 1991; Scott and Meyer, 1994; Scott and Davis, 2007), characterizes schools as

institutions with persistent patterns of social action that individuals take for granted.

Agreeing with market theorists that the bureaucratic form of schooling dominates the public school sector in the United States (and many other countries), institutional theorists take a different tack in their analysis of the education environment. For instance, the increase in bureaucratization of schools has led to an increase in rational coordination among the nested layers of the school – from the federal government to the state, districts, schools, and classrooms. According to institutional theorists such as Meyer and Rowan (1977, 1978), this bureaucratic, rational network has resulted in a system of categories or rules, called 'ritual classifications,' that define the actions of schools, teachers, and students. Over time these ritual classifications become institutionalized and accepted as the norm for what constitutes a legitimate school and its activities (Bidwell and Kasarda, 1980). Institutional theorists refer to this as *isomorphism* and have documented its diffusion both in the United States and throughout the world (Meyer and Ramirez, 2000; Bidwell and Dreeben, 2006).

School compliance to ritual classifications is important for legitimacy – more important, according to institutional theorists, than maximizing efficiency and innovations of school operations (Meyer and Rowan, 1977; Scott and Meyer, 1994). In other words, schools adapt to their environments by adopting accepted rules and structures, leaving actual classroom instruction and learning relatively unexamined and unmonitored. Such loose coupling helps schools maintain their validity (Weick, 1976) and is further promoted by schools' logic of confidence that delegates instruction to teacher professionals who ultimately control what goes on inside their classrooms. It is the teachers who typically have made the choices about what to teach and how to teach in their classrooms – a set of activities that until more recently has been beyond the purview of principals, parents, and policymakers at the district and state levels (Weick, 1976; Elmore, 2007). With the implementation of NCLB in the United States over the past decade, states and districts have attempted to guide instruction in schools through high-states accountability, but even with specific instructional materials, it is the teachers in the classrooms and their relationships with students who are making choices about what to teach, how to teach, and how to learn (see Stecher and Vernez, 2010).

DiMaggio and Powell (1983) argue that there are different types of environmental pressures on organizations to make them more similar than different. These pressures include 'coercive isomorphism,' which stems from formal and informal pressures by organizations and groups on which the school depends (e.g., federal and state mandates under NCLB), 'mimetic isomorphism,' which stems from the adoption of similar structures and practices when facing uncertain tasks; and 'normative isomorphism,' which stems primarily from professionalization of educators and professional networks.

When applied to school choice, institutional theory emphasizes that *all* schools operate within highly institutionalized environments, which define what counts as legitimate education. All types of schools, no matter the sector or organizational form, adopt rituals, norms, and myths to support their validity (Meyer and Rowan, 1977, 1978; Scott and Davis, 2007). Thus, even schools of choice pay attention to institutional rules such as teacher certification, curricular subject matter, instructional time, reasonable class size, and mostly age-based grade organization.

In short, institutional theorists argue that the institutional environment of education is so strong that significant changes in instruction are likely to be rare or short lived (see Elmore, 2007), and market theorists claim that increased choice will result in widespread autonomy promoting innovation, competition, and increased satisfaction and outcomes. Despite a couple of decades of school choice reform, researchers have not definitively supported market theory vis-à-vis institutional theory. The limited empirical research is mixed on improved and differentiated instruction and in-school organizational conditions, curriculum content, and pedagogy in schools of choice, supporting neither market nor institutional theories (see Berends et al., 2010; Lubienski, 2003; Preston et al., 2012).

Private and Catholic Schools

Many people argue that public schools are outperformed by private schools, particularly Catholic schools (Chubb and Moe, 1990; Coleman and Hoffer, 1987; Coleman et al., 1982). However, the magnitude of these effects and their implications are often the center of heated debate (see Lee and Bryk, 1993). Much of this debate focuses on whether students attending Catholic schools score higher on achievement tests than students in public schools. When comparing sector differences, there is a continuing concern about selection bias – that is, there is something different about students who attend Catholic schools vis-à-vis public schools, such as social background, motivation, values and beliefs, among other characteristics, some measureable and some difficult to measure (Goldberger and Cain, 1982).

Within these comparative analyses of school sector effects on student outcomes, researchers often focus on the issues of the *Catholic school advantage* (CSA) and the common school ideal (see also Hallinan and Kubitschek, 2010, 2012; Marks, 2009). That is, the CSA refers to the higher educational outcomes of Catholic school students compared with their public school peers, whether that be higher academic achievement or college attendance. The common school ideal, according to Hallinan and Kubitschek (2012), "signifies the goal of providing equal access to learning opportunities for all students."

In terms of academic achievement, the research to date suggests that there is variability in the effects of Catholic schools by level (e.g., high school vs elementary). For example, when considering effects on mathematics achievement, there is some evidence that the effect of attending a Catholic high school on student achievement has been consistently positive in nationally representative cohorts of high school students from the early 1980s to the present. For example, in his review of the average achievement differences among high school seniors, Hoffer (2009: p. 432) states that "the Catholic-public differences in mathematics were 0.48 SD units in the 1982 HSB survey (Hoffer et al., 1985). 0.37 SD units in the NELS:88 sample (Morgan, 2001), and 0.50 SD units in the ELS:2002 sample (Carbonaro and Covay, 2010)."

Controlling for important measures in nationally representative data from the 1980s, Coleman and Hoffer (1987) found that between grades 10 and 12, students in Catholic schools

outperformed public school students by about one grade level equivalent in both mathematics and reading. With more sophisticated multivariate models in more recent nationally representative data (2002–04), Carbonaro and Covay (2010) found that Catholic school students outperformed their public school counterparts in mathematics.

At the elementary school level, Catholic school effects seem less robust. For instance, analyzing the Early Childhood Longitudinal Study (ECLS-K), Carbonaro (2006) found that kindergarten students in public and Catholic schools experienced similar achievement gains in mathematics and general knowledge, net of other characteristics. Analyzing the ECLS-K data and the gains of students between the 3rd and 5th grades, Reardon et al. (2009) found that public school students outperformed their Catholic school peers in math but experience similar gains in reading.

Further research comparing Catholic schools at the pre-K through 8th grade levels would help shed light on the sector differences, with an emphasis on theoretical development and educational policy implications. In particular, further examination of the organizational and instructional conditions may explain sector differences at earlier grade levels and the variability between as well as within sector (Bryk et al., 1993; Berends et al., 2008). For example, at the high school level, a consistent finding in explaining the CSA has been the academic focus and more rigorous course taking patterns of Catholic school students compared with their public school peers. Yet, at the elementary grade levels, these organizational and instructional conditions have not been fully analyzed. In addition, there are several other factors – such as communities of learning and trust – that prior research and theory have pointed to but so far not fully examined as important for explaining sector differences (Bryk and Driscoll, 1988; Bryk and Schneider, 2002), social capital (Berends and Zottola, 2009; Hoffer, 2009; Marks, 2009), peer effects (Marks, 2002), or market vis-à-vis institutional hypotheses (Berends et al., 2010).

As mentioned above, to date most scholars – particularly sociologists – have focused on student outcomes in terms of standardized test scores. Others – including economists – have concentrated on college attainment, since this is an outcome of interest that has more direct economic implications for labor market participation and earnings (see Marks, 2009). Several studies analyzing nationally representative data from the 1980s to the present reveal that students attending Catholic schools are more likely to attend college (Altonji et al., 2005; Evans and Schwab, 1995; Grogger and Neal, 2000; Nguyen et al., 2006).

Internationally, there is a great deal of variation in the size of the private school sector, ranging from about 10% in the United States to 6% in the United Kingdom, 38% in Australia, 56% in Korea, 61% in Ireland, and 77% in the Netherlands (see Woessman, 2009). In their analyses of international data for 29 countries in the Programme for International Student Assessment 2003 data, Woessman et al. (2009) find that students' achievement scores are higher in countries that have a greater percentage of privately managed schools. They go on to argue important mechanisms explaining these results, including private schools' freedom to make autonomous decisions about school organization and processes and accountability systems that inform parents' choices. Although informative, it is important to know that these findings are correlational and may be subject to significant selection bias (for a review of international assessment data and private schools, see Woessman (2009)).

Charter Public Schools

Charter schools are public schools funded by the government, but they have a different governance structure compared with traditional public schools in that they are established under a charter by parents, educators, community groups, or private organizations to encourage school autonomy and innovation. In exchange for such autonomy and flexibility, charter schools are held accountable to current state and federal accountability standards, such as NCLB, which requires testing in certain grades and sets performance targets over time (overall and various subgroups). When a charter school has more students applying than there are seats available (i.e., oversubscription), the school is required to hold a lottery to select students for open seats at random.

Although the charter school sector is the fastest growing area of school choice, the evidence base is weak for scaling up charter school reform via federal policy and programs. For instance, some studies using randomized designs show modest effects on academic achievement gains for students in charter schools compared with those students who are not so enrolled (Abdulkadiroglu et al., 2009; Angrist et al., 2011; Dobbie and Fryer, 2011; Hoxby and Murarka, 2008; Hoxby et al., 2009). Other studies relying on broader samples of schools within a randomized design (Gleason et al., 2010) and those using quasi-experimental methods show mixed results for charter school effects on achievement (for a review see Betts and Tang, 2011; CREDO, 2013; Teasley, 2009).

Although it is important to understand that overall charter school studies show that effects on achievement are mixed (some positive, some negative, and some neutral), it is important to note that some studies have found significant and substantial positive effects of charter schools, particularly in urban areas where it has been difficult to implement meaning educational reforms. For example, comparing students who won and lost charter school lotteries, Hoxby et al. (2009) found that charter students outscored the comparison group in both mathematics and English. The authors noted that students who attended charter schools in New York City over a longer period of time (e.g., kindergarten through 8th grade) matched the mathematics performance gains of their peers in affluent suburban schools – what they called the closing of the 'Harlem–Scarsdale' achievement gap. Dobbie and Fryer (2011), who examined students who won and lost the charter school lotteries in the Harlem Children's Zone, found that the effects of charter elementary schools were large enough to close the racial achievement gap across subjects – i.e., students gained about 0.20 of a standard deviation a year in both mathematics and English/language arts. Large effects of charter schools have also been found in Boston (Angrist et al., 2011).

Although studies of school choice shed some light on the main effects in different locales, they provide limited information about the schools as organizations and the conditions within them that may promote student achievement,

particularly the curriculum and instruction that is most likely to affect student learning. Many researchers and policymakers advocate looking inside schools to better understand the conditions under which schools of choice have (or do not have) positive effects on achievement, pointing to the importance of detailed information about curriculum, instruction, organizational conditions that promote achievement, and teacher characteristics and qualifications (Berends et al., 2008, 2010; Betts and Loveless, 2005; Gill et al., 2007; Zimmer and Buddin, 2007, 2008; Zimmer et al., 2003). To date, however, these calls to look at the organization of schooling within the charter sector have not been heeded, by and large – suggesting an important avenue for future research.

This is an important research agenda for cross-national comparisons as well, for we know that many other countries have 'independent schools' that are publicly funded, but privately managed. For instance, in the United Kingdom, there are several models that represent a basic departure from the "'pure model' of sole public funding and sole public provision" of educational services (Brewer and Hentschke, 2009: p. 228). These models of departure include the foundation schools, grant-maintained schools, city technology schools, and academies, and school founders in a many of these cases can be for-profit businesses or faith-based organizations. School founders can play a major role in determining the instructional design, curriculum, and appointing members to the governing body if the founders put in an investment of 10% of the academies' capital costs (or about £2 million, whichever is less).

In the Netherlands, independent schools are the norm; the government provides financial support to private schools (including religiously affiliated institutions). Schools have control over curriculum and the hiring of teaching staff, but they cannot exceed the national standard of student–teacher ratio. Another important constraint is the national curriculum standards and national exit exams at the end of primary and secondary schooling (Brewer and Hentschke, 2009).

Likewise, more recently in Qatar there is a significant growth in publicly funded, but privately operated independent schools (or charters). First introduced in 2002, about half of the nation's students were enrolled in independent schools by 2008. Brewer et al. (2007) find that the founders varied from those from the business sector to former school administrators and educational ministry officials.

As these examples reveal, there is much to learn about how independent (or something very similar to charter schools) are operated and how they affect students' academic and social outcomes.

Choice Scholarships and Voucher Programs

Besides the changes in the charter school sector, another choice option is vouchers, or school choice scholarships, that provide parents with public funding to send their children to the school of their choice, which includes public or private schools (religious or nonreligious). These public vouchers are often means-tested and are allocated to families for tuition payments to pay for part or all of the tuition. Vouchers have also been highly contested and debated in educational policy, the media, and research communities. For instance, studies in the 1990s of the Milwaukee voucher program, researchers disagreed about the effects of the program on student outcomes (see Berends et al., 2011). Although policymakers suspected that evaluation of the program would settle disputes about the effects of vouchers on students, the research findings instead were nuanced and mixed (for review, see Figlio, 2009; Zimmer and Bettinger, 2008).

With the expansion in the number of voucher programs, the research addressing the effects of these programs has increased as well. However, the research portrays a mixed view of voucher impacts (Figlio, 2009; Zimmer and Bettinger, 2008). The first study of a school voucher program in the United States was the official evaluation of the pioneering Milwaukee Parental Choice Program, 1990–95 (see Witte, 2000). Subsequent work analyzed a portion of the data generated by that evaluation, and was reported in Greene et al. (1999b) and Rouse (1998). These studies were different from Witte in their methodological approaches and, therefore, the findings reported differed. Based on regression models strengthened with Heckman selection corrections, the Witte work found generally no systematic differences on student achievement outcomes between voucher and public school students. The Greene et al. analysis was based on a subset of voucher participants who had won their voucher via a lottery system to a small number of oversubscribed private schools, finding positive achievement impacts associated with participation. Rouse employed a series of quasi-experimental approaches from student fixed effects and instrumental variable designs, finding no effect in reading but positive achievement impacts in math.

These differences between findings of positive and no achievement effects have since been reflected in other studies of voucher programs. For example, Greene (2001) found positive achievement impacts from an experimental analysis of the privately funded voucher program in Charlotte, a result generally supported by Cowen (2008) using more sophisticated statistical models. Howell et al.'s (2002) primary analysis of lottery-based privately funded programs in New York City, Washington, DC, and Dayton, Ohio revealed positive student achievement outcomes for African-American students, but not for the overall sample, a finding both confirmed (Barnard et al., 2003) and questioned (Krueger and Zhu, 2003) by subsequent analysts of the New York data. Studies of the Cleveland Scholarship Program similarly found both positive impacts for voucher students (Greene et al., 1999b) and no significant differences (Metcalf et al., 2003), findings that differed due to study design and sample. Using a regression discontinuity approach on the statewide voucher system in Florida, Figlio and Hart (2011) found that the program generated statistically significant positive impacts on student reading achievement, at least for students near the income-eligibility ceiling. Witte et al. (2012) reported that Milwaukee voucher students on average gained more than a matched sample of public school students in reading but not in math in the final year of that 4-year evaluation. They noted that a new high-stakes testing policy may have been partly or wholly responsible for the voucher gains.

The evaluation of the first federally funded voucher program in Washington, DC relied on an experimental design based on scholarship lotteries (Wolf et al., 2010, 2011). The series of

reports described significant achievement gains in reading in the third year of the evaluation but no significant reading impacts in other years, including the fourth and final year, or in math in any year. This same study revealed significant gains in voucher students' high school graduation rates. Cowen et al. (2013) reported gains in educational attainment from the Milwaukee voucher program, both in terms of rates of high school graduation and 4-year college enrollment. Recently, Chingos and Peterson (2012) found that African-Americans who participated in the New York City privately funded voucher experiment enrolled in college at higher rates than the experimental control group, though there were no significant attainments effects of the program on the entire sample of students.

Internationally, the research on voucher programs is more positive in terms of effects on student achievement scores. Reviewing studies from Chile, Columbia, Denmark, South Korea, Sweden, the Netherlands, and Denmark, Barrera-Osorio and Patrinos (2009) summarize the international research on vouchers as follows: "The most rigorous studies available show that voucher programs lead to significant improvements in access to secondary schooling for relatively poorer students; these programs also lead to significant increases in test scores. Additionally, studies show that voucher recipients are more likely to complete secondary school, enter university, postpone marriage, and increase their earnings" (p. 339).

Similar to the research on charter and independent schools, there have been very few studies that examined the specific learning conditions that students experienced in their schools of choice vis-à-vis comparable students in traditional public schools (Figlio et al., 2013; Zimmer and Bettinger, 2008). Although such studies are difficult to design and implement, more research is needed on school and classroom experiences to understand the conditions under which voucher programs provide more meaningful and substantive learning opportunities (or not).

Education Tax Credits

Another school choice option that has increased dramatically over the past decade is providing education tax credits to businesses and individuals. Parents can receive a tax credit or deduction for educational expenses (tuition, books, supplies, transportation), and businesses can receive a tax credit for making donations to nonprofits called SGOs, which use the funds for private school student scholarships. Often education tax credits are seen as equivalent to vouchers in that they provide students with funds to attend private schools; it is the transfer mechanisms that differ. In addition, education tax credits have been seen as a more palatable way to get legislation passed in different states because of the controversies and debates around vouchers and the direct provision of public funds to attend private schools. Education tax credits are a more indirect transfer of public funds.

Perhaps because education tax credits seem more acceptable in state legislatures and are not under scrutiny like voucher programs, there has been a great deal of policy activity at the state level since the 1980s, and certainly over the past few years (Huerta and d'Entremont, 2007; Schaeffer, 2009). For example, there were a total of 26 tax credit scholarship bills in 2008, and over a 3-year period this number more than doubled to 53 in 2011 (Berends, 2014).

The research on education tax credits is very limited (as mentioned by Belfield, 2005; Huerta and d'Entremont, 2007; Schaeffer, 2009; Zimmer and Bettinger, 2008), probably because education tax credits are often equated with vouchers. Similar to voucher programs, which in the end result in students transferring from the public to private sector, more information is needed about the instructional practices and school organizational conditions that students using tax credits experience compared with their counterparts. Some questions that might further our understanding of tax credit effects include: Who chooses to apply and use a tax credit? What are the characteristics of students and their families receiving tax credits? To what schools do such students apply and attend? What are the learning opportunities in these schools vis-à-vis the schools that students attended before? What are the differences in the organizational and instructional conditions in the schools of destination (attending with vouchers) compared with schools of origin (where students attended previously)?

Unfortunately, the research appears to be less than conclusive – 'unfortunate' because this provides fodder for continued debate at different levels of policy about whether or not to scale up these choice options. What is needed is more systematic research that looks at the educational trajectories of students in choice and nonchoice schools with data not only on test score gains and graduation rates, but other noncognitive measures of student outcomes (e.g., behavior, engagement, motivation, educational and occupational expectations). In addition, more systematic information needs to be gathered from the choice and nonchoice learning environments, including not only instructional conditions but also differences in the social organization of schools (see Berends et al., 2010).

Homeschooling

Homeschooling is one of several parental choice options, and often, it is overshadowed by other aspects of choice, such as private or Catholic schools, charter schools, voucher programs, and tuition tax credits (see Berends et al., 2009). Nearly 3% of the K-12 student population in the United States is homeschooled – making the homeschooling sector nearly as large as the sectors of Catholic schools and charter schools. Yet, homeschooling remains one of the most understudied areas of school choice. Unlike research on other areas of school choice – such as the research on charter schools and voucher programs that has produced a growing evidence base for understanding impacts on students – the research on homeschooling is sparse and disappointingly weak.

We do know a few descriptive aspects of homeschoolers. For instance, the families that tend to homeschool their children tend to be better educated and solidly middle class compared with parents who do not homeschool, and this status is achieved with only one wage earner, typically the father (Murphy, 2012). Moreover, homeschool families also tend to have cohesive marriages and are overwhelmingly Protestant Christians, often fundamentalist (Murphy, 2012).

In terms of academic achievement differences between students who are and are not homeschooled, the data are extremely limited, but research suggests that homeschooled students compare well when examining national norms for test scores or when looking at college entrance scores, such as the ACT or SAT (Murphy, 2012). For example, Ray (2010) found that homeschool students performed above the 80th percentile in reading, language, mathematics, science, and social studies. Belfield (2004) found that homeschooled students outperformed public school students on the SAT; for instance, homeschoolers scored 527 on the mathematics portion and 567 on the verbal portion of the SAT compared with public school students' scores of 510 in math and 503 in verbal. However, Belfield was careful to point out the serious issues of self-selection of SAT test-takers and the lack of controls for relevant measures when looking at these differences.

We need to know a great deal more about homeschooling on students' social, behavioral, and academic outcomes and its variation in the United States and other countries. It would be helpful to gathering longitudinal data about households, families, and children across different homeschooling contexts to inform this significant gap in the empirical base along with comparisons to other parental choice options, including traditional public schools. Researchers would make contributions by also examining 'dosage.' By that I mean that it is not clear how long students typically stay in homeschooling situations and whether that matters for important youth outcomes. In future research, gathering information about how long students are homeschooled and why parents make those decisions would provide important new insights into this understudied area.

Future Research Possibilities

As mentioned throughout, additional research is critical for understanding the various effects of school choice reforms, particularly as the landscape of choice reforms continues to expand in a dramatic fashion for students around the world. Such research can make significant contributions to educational policy related to private or Catholic schools, charter/independent schools, vouchers, education tax credits, and homeschooling. An important component of this future research should address questions that go beyond horse races between sectors (e.g., charter and non-charter students, voucher and non-voucher students, students benefiting from tax credits vis-à-vis those who do not, and homeschooler outcomes vis-à-vis public school student outcomes). Rather, understanding the conditions under which these choice options are effective or not will help push policy debates forward. Further cross-national research is also important to understand the school choice policy conditions related to student outcomes in different contexts. Such research will hopefully cumulate to further systematic knowledge-building and revision of policies and theories within research and policy communities, so that there is systematic growth in our understanding of the policies and research (see Cohen, 2003). In the future, research is needed not only to inform the policy debates about school choice, but to examine the effects on students who have historically not had access to the resources and educational opportunities that lead to future educational and adult attainments.

School Effectiveness Research

Jaap Scheerens, Faculty of Behavioral Sciences, University of Twente, Enschede, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

School effectiveness research is described as the scientific approach to determine the causal influence of malleable conditions of schooling. The article describes how different strands of school effectiveness have developed and are now increasingly combined into more integrative approaches. The knowledge base of school effectiveness research is discussed on the basis of the results from meta-analyses and international comparative assessment studies. The size and educational relevance of the effects of malleable school conditions is still contested. Theory-based interpretation and theory-driven research are a relatively neglected area in this field. Promising developments are found in conceptual models and application of more established organizational and economic theories. Methodologically the field is likely to benefit from more rigorous research design, such as quasi-experimental evaluations of school improvement projects and randomized field trials.

School Effectiveness and School Effectiveness Research

In the most general sense 'school effectiveness' refers to the level of goal attainment of a school. Although average achievement scores in core subjects, established at the end of a fixed program, are the most probable 'school effects,' alternative criteria like the responsiveness of the school to the community and the satisfaction of the teachers may also be considered.

Assessment of school effects occurs in various types of applied contexts like the evaluation of school improvement programs or comparing schools for accountability purposes, by governments, municipalities, or individual schools.

School effectiveness *research* attempts to deal with the causal aspects inherent in the effectiveness concept by means of scientific methods. Not only is assessment of school effects considered, but particularly the attribution of differences in school effects to malleable conditions. Usually, school effects are assessed in a comparative way, e.g., by comparing average achievement scores between schools. In order to determine the 'net' effect of malleable conditions, like the use of different teaching methods or a particular form of school management, achievement measures have to be adjusted for intake differences between schools. For this purpose student background characteristics like socioeconomic status, general scholastic aptitudes, or initial achievement in a subject are used as control variables. This type of statistical adjustment in research studies has an applied parallel in the strive for 'fair comparisons' between schools, known under the label of '*value-added.*'

School effectiveness research is often compared with the related field of school improvement. Seen from a research perspective the differences are gradual, with the additional focus on strategies for educational change in school improvement studies being the major difference (Scheerens, 2013).

Strands of Educational Effectiveness Research

School effectiveness research has developed as a gradual integration of several research traditions. The roots of current 'state-of-the-art' school effectiveness research are sketched by briefly referring to each of these research traditions. Integration implies that school effectiveness research, specifically focused at the effects of school level factors, is now often embedded in multilevel *educational* effectiveness models. This issue is further addressed in the Section Strands of Educational Effectiveness Research, but it implies that certain looseness in terminology will be used as far as the terms school effectiveness and educational effectiveness are concerned. When speaking of school effectiveness studies that have addressed, in addition to school factors, teaching conditions, either at classroom level are aggregated up to the school level, will be included under this label.

The elementary design of school effectiveness research is the association of hypothetical effectiveness enhancing conditions of schooling and output measures, mostly student achievement. A basic model is from systems theory, where the school is seen as a black box, within which processes or 'throughput' take place to transform inputs into outputs. The inclusion of an environmental or context dimension completes this model (see **Figure 1**). The major task of school effectiveness research is to reveal the impact of relevant input characteristics on output and to 'break open' the black box in order to show which process or throughput factors 'work,' next to the impact of contextual conditions. Within the school it is helpful to distinguish a school and a classroom level and, accordingly, school organizational and instructional processes.

Research tradition in educational effectiveness varies according to the emphasis that is put on the various antecedent conditions of educational outputs. These traditions also have a disciplinary basis. The common denominator of the six areas of effectiveness research that will be distinguished is that in each case the elementary design of associating outputs or

Figure 1 A basic systems model of school functioning.

Table 1 General characteristics of types of school effectiveness research

	Independent variable type	*Dependent variable type*	*Discipline*	*Main study type*
1. (Un)equal opportunities	Socioeconomic status and IQ of pupil, material school characteristics	Attainment	Sociology	Survey
2. Production functions	Material school characteristics	Achievement level	Economics	Survey
3. Evaluation compensatory programs	Specific curricula	Achievement level	Interdisciplinary pedagogy	Quasi-experiment
4. Effective schools	'Process' characteristics of schools	Achievement level	Interdisciplinary pedagogy	Case study
5. Effective instruction	Characteristics of teachers, instruction, class organization	Achievement level	Educational psychology	Experiment observation
6. System level effectiveness	System level policies and institutional arrangements	Achievement and attainment	Economics	Background studies based on international assessment programs

outcomes of schooling with antecedent conditions (inputs, processes, or contextual) applies.

The following research areas or research traditions can be distinguished:

1. Research on equality of opportunities in education and the significance of the school in this.
2. Economic studies on education production functions.
3. The evaluation of compensatory programs and school improvement programs.
4. Studies of unusually effective schools.
5. Studies on the effectiveness of teachers, classes, and instructional procedures.
6. Studies on the effectiveness of system level policies and institutional arrangements.

For a further discussion of the first five of these research traditions the reader is referred to Scheerens et al. (2003: Chapter 11). A schematic characterization of research orientation and disciplinary background is given in **Table 1**. The sixth research area is an emerging field, which is very much stimulated by international assessment programs, such as TIMSS and PISA. System level variables that have been addressed in these kinds of studies are decentralization, choice, and accountability arrangements in national educational systems (cf Woessmann et al., 2009). Scheerens et al. (2012), in a study that used PISA 2009 data, investigated more complex models in which indirect effects of system level factors through intermediary school conditions on student performance were computed.

A very interesting methodological development is the new interest in the use of randomized field trials in school effectiveness research (cf Bosker, 2011). Many relevant examples are presented on the website attached to the biannual SREE (Society for Research on Educational Effectiveness) conferences (https://www.sree.org/).

Integrated School Effectiveness Research

In recent school effectiveness studies these various approaches to educational effectiveness have become integrated. Integration was manifested in the conceptual modeling and the choice of variables. At the technical level multilevel analysis has contributed significantly to this development. In contributions to the conceptual modeling of school effectiveness, schools became depicted as a set of 'nested layers' (Purkey and Smith, 1983), where the central assumption was that higher organizational levels facilitated effectiveness enhancing conditions at lower levels (Scheerens and Creemers, 1989). In this way a synthesis between production functions, instructional effectiveness, and school effectiveness became possible, by including the key variables from each tradition, each at the appropriate 'layer' or level of school functioning [the school environment, the level of school organization and management, the classroom level, and the level of the individual student]. Conceptual models that were developed according to this integrative perspective are those by Scheerens (1990), Creemers (1994), Stringfield and Slavin (1992), and Creemers and Kyriakides (2008). By way of illustration the Scheerens model is shown in **Figure 2**.

Exemplary cases of integrative, multilevel school effectiveness studies are those by Mortimore et al. (1988), Brandsma (1993), Hill et al. (1995), Sammons et al. (1995), and Grisay (1996). The study by Borman et al. (2003) provides a review and meta-analysis of evaluations of Comprehensive School Reform (CSR) projects. CSR projects form a very interesting blending of school effectiveness and school improvement, as well as an application of integrating effectiveness enhancing conditions at school context, school, and classroom level.

The Knowledge Base on School Effectiveness

Review and meta-analyses on school effectiveness, e.g., Wang et al. (1993) and Scheerens and Bosker (1997), indicate that resource-input factors on average have a negligible effect, school factors have a small effect, while instructional variables have an average to large effect. Another feature, noted by Scheerens and Bosker (1997), is a remarkable difference between the relatively small effect size for the school level variables reported in meta-analyses and the degree of certainty

Figure 2 An integrated model of school effectiveness. From Scheerens, J., 1990. School effectiveness and the development of process indicators of school functioning. School Effectiveness and School Improvement, 61–80.

and consensus on the relevance of these factors in the more qualitative research reviews.

The same kind of relative ordering of effect sizes is evident from more recent meta-analyses, as those by Hattie (2009) and Scheerens et al. (2007). Still as it comes to effect sizes, important differences are reported in different meta-analyses. Hattie (2009) provides massive quantitative evidence on the association of numerous school, teacher, and teaching variables with student achievement. Average effect sizes for school, curriculum, teacher, and teaching factors in terms of the *d* coefficient (standardized difference between means) reported by Hattie are 0.23, 0.45, 0.49, and 0.43, respectively (Hattie, 2009: pp. 74, 109, 130, 162, 201). According to Cohen (1988), effect sizes of 0.2 are considered small, 0.5 medium, and 0.8 large. According to these standards the average effect sizes should be considered as slightly below medium. Still, meta-analyses that are carried out by European authors show effect sizes that are even lower; see for example Witziers et al. (2003), Scheerens et al. (2007), Seidel and Shavelson (2007), and Creemers and Kyriakides (2008). By way of illustration some of the results on key variables like educational leadership, evaluation and monitoring, learning time, structured teaching, and quantity of teaching are compared. For educational leadership Hattie (2009: p. 82) reports a coefficient *d* of 0.36, which expressed as a correlation coefficient is 0.18; Scheerens et al. (2007) and Creemers and Kyriakides (2008: p. 202) report effects (correlations) of 0.05 and 0.07, respectively. For feedback and monitoring at classroom level from Hattie's results, an average effect of 0.33 (correlation) can be computed. (This is the average of effect sizes found for 'feedback' (p. 173), 'frequent testing' (p. 178), and 'formative evaluation' (p. 181), expressed as a correlation.) Scheerens et al. (2007) and Seidel and Shavelson found effects of 0.07 and 0.01, respectively. Using structured teaching as an overarching label, Hattie reports an effect size comparable to a correlation of 0.30 for direct teaching. Creemers and Kyriakides found an effect size of 0.17 for 'quality of teaching,' while Scheerens et al. (2007) and Seidel and Shavelson (2007) report effects of 0.09 and 0.02, respectively. Variables associated with quantity of teaching, time on task, and opportunity to learn show effect sizes of 0.17 (Hattie, 2009: p. 184; Creemers and

Kyriakides, 2008: p. 201), but 0.08 and 0.03 in the studies by Scheerens et al. (2007) and Seidel and Shavelson (2007). A more extensive table with comparisons of results from meta-analyses is provided in Scheerens et al. (2011: p. 144).

According to established scientific standards the effect sizes for the key school and teaching variables are medium when one considers the results by Hattie and small when one considers the other meta-analyses. One of the explanations Hattie (2009: p. 202) offers for the differences in effect sizes between his results and those by Seidel and Shavelson is that these latter authors have used only studies that controlled for student prerequisites. This could be seen as a sign that the more Europe-based studies used stricter quality controls in selecting studies, and might therefore have more credible results. The other explanation might be that effect sizes in the USA, Great Britain, and Australia are higher, perhaps due to greater variability in processes and outcomes.

Results from international studies indicate that the generalizability of educational effectiveness outcomes is rather poor. Results based on PISA, for example, show that the school variable that did best in PISA 2000, 'orderly climate,' was significantly associated with reading literacy achievement in just 11 out of 37 countries (Luyten et al., 2005).

Interesting debates can be started about further interpretation of the effect sizes. It could be argued that even 'small' effects are educationally relevant when compared, for example, to the magnitude of achievement gain in 1 year of schooling (cf Baumert et al., 2006). This is beyond the scope of this article. Still the excursion into the world of quantitative meta-analyses gives reason to be prudent in the interpretation of the strength of the educational effectiveness knowledge base as far as positive process/outcome associations are concerned.

Conceptual Models and Theory in School Effectiveness Research

Usually the field of educational effectiveness research is considered as rather a-theoretical. This impression is enforced in a 'research mapping' study by Nordenbo et al. (2009). According to this study, out of 111 empirical school effectiveness studies only 23 made explicit reference to theory or a conceptual model.

According to Snow (1973) theory development is to be seen as a continuum, ranging from relatively simple generalizations to axiomatic theory. Conceptual models have a place on this continuum. The 'Dynamic Model' by Creemers and Kyriakides (2008) illustrates various applications of theory. Its micro level core is based on the Caroll model, which in turn has a connection with learning theory. Next the model is an example of conceptual mapping, using a multilevel framework and various metatheoretical concepts, such as consistency across levels and control. A major challenge of this and other multilevel conceptual models is to understand the way factors at different levels interact and mediate achievement outcomes. Finally, the Dynamic Model represents an elaborate measurement model of effectiveness enhancing processes. The pragmatic road ahead for educational effectiveness would seem to be the continued connection of conceptual models, such as the Dynamic Model, and advanced statistical analysis techniques, such as multilevel structural equation modeling. The knowledge about 'indirect effects' provides more insight into the mechanisms by which effectiveness enhancing conditions work. Interesting examples are provided in indirect effect models of school leadership, where instructional conditions gradually become better integrated as important intermediary factors; cf Heck and Moriyama (2010), Louis et al. (2010), and Scheerens (2013).

Two other conceptual models that have been used as a basis for school effectiveness research are the *Quinn and Rohrbaugh Competing Values Framework* as applied by Cameron and Whetten (1983) and Quinn and Rohrbaugh (1983), and the concept of *High Reliability Organizations*, as applied to schools by Stringfield et al. (2008).

The Competing Values Framework is based on alternative models of organizational effectiveness. Each model is based on long-standing schools of thought in organizational and management science: the idea of economic rationality and rational planning, the idea of organizations as open systems, the human relations orientation, and the idea of formalized structure, the bureaucracy. Quinn and Rohrbaugh derive four distinct models from these basic orientations, the Rational Goal (RG) Model, the Open Systems (OS) Model, the Human Relations (HR) Model, and the Internal Process Model (IP). Each is oriented toward a specific effectiveness criterion: RG toward primary production, OS toward adaptability and responsiveness toward the environment, HR toward staff job satisfaction, and IP toward formal structures and procedures. Griffith (2003) uses this framework to map malleable variables that have received empirical support in school effectiveness research according to each of these four models. For example, optimizing learning time is seen as a measure that fits RG, stimulating parental involvement as belonging to OS, participative leadership is subsumed under the HR model, and creating an orderly atmosphere is seen as a measure fitting the IP approach. By means of path analysis Griffith models the effects of each of the four organizational models on student achievement. The Quinn and Rohrbaugh framework has also been used, with varying success, to model direct and indirect effects of school leadership (e.g., Ten Bruggencate, 2009; for an overview of studies see Scheerens, 2012). By subsuming specific effectiveness enhancing variables under four broader concepts, this approach succeeds in providing a more parsimonious conceptualization of educational effectiveness. The four orientations to organizational effectiveness can easily be interpreted as different strategies to school improvement.

The second theoretical approach that was represented in the set of studies covered by Nordenbo et al. (2009) and which can be associated with the Quinn and Rohrbaugh framework is the work on schools as High Reliability Organizations (Stringfield et al., 2008). High Reliability Organizations operate in a context where failure to attain the key goals would be disastrous. Specific characteristics are clear and finite goals, alertness to surprises and lapses, the imperative to identify flaws, use of powerful databases, standard operating procedures, rigorous evaluation, and hierarchical structure, through collective decision making. High Reliability Organizations are very much in line with the IP Model, of the Competing Values Framework, and are aligned to the RG Model as well. Bureaucratic structuring and formalization of procedures are at the heart of this approach to school improvement.

Despite these interesting examples, a more fundamental theory-oriented basis for school effectiveness research is still an unaccomplished ideal. Crucial ingredients for bringing this about would be a comprehensive reflection on the knowledge base, stricter formalization of key associations in multilevel conceptual models, and interpretation of the key findings against the background of more established theory and constructs, e.g., loose coupling versus alignment. An interesting complementary perspective in theory-oriented work could be guided by conceptualization and empirical data on school failure and mechanisms that would create 'ineffectiveness': e.g., Stringfield (1998) and Scheerens (2014).

The Future of School Effectiveness Research

From this article it could be concluded that school effectiveness research can be defined in a broad and a narrow sense. In the broadest sense one could refer to all types of studies which relate school and classroom conditions to achievement outcomes, preferably after taking into account the effects of relevant student background variables. In a narrower sense state-of-the-art integrative school effectiveness studies and fundamental studies could be seen as the core.

Following the broader definition the future of school effectiveness studies is guaranteed, particularly in the sense of 'applied' studies, like cohort studies, large-scale effect studies carried out for accountability purposes, monitoring studies, and (international) assessment studies.

State-of-the-art, fundamental, and foundational school effectiveness studies are a much more vulnerable species, one of the major difficulties being the organizational complexity and costs of the 'state-of-the-art' types of study. Given the shortage of these kinds of studies the more fundamental and foundational types of studies are likely to be dependent on the quality of data sets that have been acquired for 'applied purposes.'

Therefore the best guarantee for continued fundamental school effectiveness research lies in the enhanced research technical quality of applied studies. Examples are quasi-experimental evaluation of carefully designed school improvement projects and randomized field trials on specific effectiveness enhancing factors, such as longer school days, alignment between content taught and content tested, result-oriented leadership, and focused teaching.

The coherence of the field is served by regular comprehensive reviews, such as the three state-of-the-art reviews, published in the journal *School Effectiveness and School Improvement*: Reynolds et al. (2012), Muijs et al. (2012), and Hopkins et al. (2012).

School Environment for LGBTQ/Sexual Minority Youth

Stephen T Russell, Amanda M Pollitt, and Jennifer M Hoenig, University of Arizona, Tucson, AZ, USA

Abstract

There has been growing attention in the last decade to the school experiences of lesbian, gay, bisexual, transgender, queer, and questioning (LGBTQ) or sexual minority youth. Unlike youth of prior generations, contemporary LGBTQ youth have opportunities to 'come out' in their families, communities, and schools, a factor that has changed the climate at school for all students. This article provides an overview of homophobia and bullying at school. Consistent with recent research in this area, it considers both individual student experiences as well as broader questions about school climates of safety and support for LGBTQ students and their heterosexual allies. A number of strategies to promote positive school climates for LGBTQ and all students have been proposed in recent years, and are reviewed: nondiscrimination and antibullying laws and policies, curricular inclusion, and school-based clubs such as gay-straight alliances. In closing, implications are considered for future research, policies, and programs to support the health and development of LGBTQ youth in schools.

In recent years there has been growing public awareness of lesbian, gay, bisexual, transgender, queer, and questioning (LGBTQ) or sexual minority youth and their experiences at school. News reports of the deaths by suicide of gay boys following chronic harassment at school brought unprecedented attention to the issue of homophobic school bullying, as well as to the broader issue of the degree to which school climates are safe and supportive of LGBTQ students. In the same period there have been controversies in many communities, also played out in news media, about challenges to long-standing heteronormative practices of schools: whether students can take same-sex dates to the prom; whether a boy can be a homecoming queen; and whether students can choose their gender presentation in senior class portraits. This public attention is in stark contrast to the silence that many LGBTQ students in prior cohorts experienced at school: For many generations they were simply invisible.

This growing public awareness and understanding of LGBTQ students and their experiences at school has emerged in part because LGBTQ youth are 'coming out' (acknowledging and disclosing their sexual and gender identities to others) at younger ages. Broad social acceptance has shifted during this period, as evidenced by multiple factors, most notably the growing public affirmation of marriage for same-sex couples. Yet for youth there is a tension between growing social acceptance on one hand, and the persistent heteronormativity of schools on the other. Thus, even as acceptance grows for LGBTQ individuals, schools remain places where homophobia, heterosexism, and discrimination continue to exist. The norms, beliefs, and attitudes held by peers, teachers, and administrators shape a school's climate. A growing body of literature has demonstrated that positive school climate supports positive development (Birkett et al., 2009). However, numerous studies have indicated that the climate of schools in the United States is hostile and unsafe for many LGBTQ youth.

We consider the lives of contemporary LGBTQ youth: their coming out in today's context, and their experiences at school. After providing an overview of homophobia and bullying at school, we shift from a focus on individual student experiences to consider broader questions about school climates of safety and support for LGBTQ students and their heterosexual allies. A number of strategies to promote positive school climates for LGBTQ and all students have been proposed in recent years: nondiscrimination and antibullying laws and policies, curricular inclusion, and school-based clubs such as gay-straight alliances (GSA). Finally, we consider implications for future research, policies, and programs to support the health and development of LGBTQ youth in schools.

Contemporary LGBTQ Youth

There have been dramatic social changes in attitudes toward homosexuality during recent decades, propelled in part by a growing number of positive LGBTQ role models, including positive portrayals of LGBTQ individuals and families in television, film, and literature. At the same time there has been growing advocacy and legislation related to LGBTQ people and their lives, most notably related to marriage, which is now legal for same-sex couples in multiple states of the United States and countries around the world (Loftus, 2001). Parallel to increasing social acceptance, LGBTQ adolescents come out at earlier ages compared to youth in prior decades, and many disclose their sexual identities in the context of supportive environments (rather than in the context of alienation and shame, as was often the case for prior cohorts). Recent young adult cohorts report coming out between ages 16 and 17 compared to older adult cohorts who report having come out between the ages of 24 and 27 (Grov et al., 2006); notably, patterns of sexual identity and behavior, as well as development of sexual identity milestones such as coming out, show few differences across racial/ethnic groups (Rosario et al., 2004). Some studies show that youth are coming out at even younger ages, including during middle school (Poteat and Anderson, 2012).

At the same time, youth generally report stronger prejudice and more engagement in social exclusion at younger ages. These trends in prejudice and social exclusion may have multiple origins. On one hand there are significant cognitive and developmental changes during adolescence that enable teens to evaluate human rights, fairness, and prejudice with more sophistication as they age. Other explanations emphasize self-consciousness and peer regulation that are heightened during the early adolescent years. Whether explained by cognitive, interpersonal, or social developmental factors,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10243-0

compared to their older counterparts, younger adolescents are less adept at navigating social differences that may involve stigma or prejudice. Thus, as youth have begun to come out at younger ages across recent years, this downward trend in age at coming out collides with age-related trends in homophobia. Considering these two competing patterns – the historical trend that LGBTQ youth are coming out at younger ages and the developmental course of prejudicial attitudes and behaviors – it is likely that contemporary youth's school experiences may be more characterized by homophobia and prejudice than was true for prior cohorts, despite the broad trends in social acceptance of LGBTQ people and issues (Poteat and Russell, 2013).

Homophobia and Bullying

There is a broad discourse regarding homophobia and bullying; in the research literature studies have considered multiple relevant dimensions: homophobic epithets (name-calling; use of the phrase 'that's so gay'), perceptions of safety and belonging, physical and verbal harassment, and bullying and cyberbullying in schools. Homophobic epithets are ubiquitous in US high schools. According to a report by the Gay, Lesbian and Straight Education Network (GLSEN; Kosciw et al., 2012), "84.9% of students heard 'gay' used in a negative way (e.g., 'that's so gay') frequently or often, and 91.4% reported that they felt distressed because of this language" (p. xiv). In addition, over two-thirds heard other homophobic remarks (e.g., 'dyke' or 'faggot') frequently or often while 61.4% heard negative remarks about gender nonconformity. Students report homophobic language in school not only from peers, but from educators as well: Over half of students reported hearing negative remarks about sexual orientation and gender nonconformity from teachers or other school staff.

From the perspective of many youth, the phrase 'that's so gay' is not discriminatory but is understood as a general put-down; this perspective has been acknowledged by scholars (e.g., McCormack, 2012). Yet perspective and perception matters; there is clear evidence that for LGBTQ young people, 'that's so gay' is interpreted as personally undermining or distressing (Kosciw et al., 2012). The GLSEN report documents a slow but steady decline in the frequency of expressions such as 'that's so gay' since 2001 (Kosciw et al., 2012). This result comes from a large nationwide study of LGBTQ students, and is the first empirical indication that this form of homophobia in schools may be on the decline. Although the use of this phrase seems to be declining, the same study showed that negative remarks about gender nonconformity have changed very little. Thus, although there may be increasing understanding that the use of the word 'gay' as a put-down is problematic, a trend which follows the growing social acceptance of LGBTQ people and issues, there appears to be little change in adolescents' sensitivity to negative remarks regarding conformity to the boundaries of masculinity and femininity.

Homophobic language at school contributes to school climates that may be unsafe for LGBTQ students. In fact, feeling unsafe at school is a critical issue for many sexual and gender minority students: 63.5% of LGBTQ students felt unsafe because of their sexual orientation, and 43.9% because of their gender expression. More than one-third (38.3%) were physically harassed in the past year because of their sexual orientation, and 27.1% because of their gender expression (Kosciw et al., 2012). This leads to multiple negative outcomes for sexual and gender minority students: Sexual minority students who experience high levels of victimization are more likely to skip school because they fear for their safety, smoke cigarettes, drink and use substances more often, and engage in suicidal behavior compared to nonsexual minority students (Bontempo and D'Augelli, 2002). Further, LGBTQ youth who are gender nonconforming are at risk for depression and life dissatisfaction due to LGBT-specific harassment (Toomey et al., 2010).

LGBTQ youth are frequently victims of harassment, discrimination, and violence within schools. This harassment takes on many forms in addition to bias-based language, including verbal teasing, bullying, and physical aggression (Russell et al., 2010). GLSEN reported that over 50% of LGBTQ students were verbally harassed and over 25% were physically harassed (Kosciw et al., 2012). However, there are group differences between sexual and racial/ethnic minorities: Bisexuals experience higher levels of victimization than other sexual minority groups and white and Latino adolescents experience higher levels of victimization than Black and Asian adolescents (Russell et al., in press). In a study of California schools, white students reported more sexual identity-based victimization than students of color (Russell et al., 2009). Similar patterns of victimization have been found in school samples in other countries. For example, homophobic behaviors are reported to be widespread among Italian students, with verbal and physical abuse being commonplace within schools (Prati et al., 2011).

Constant exposure to these conditions has been shown to have negative consequences, as discrimination and stigmatization within schools can have a negative impact on the mental health of youth. A number of studies have documented associations between school bullying, victimization, and abuse and compromised mental health among LGBTQ youth. In particular, D'Augelli and colleagues (2002) found that youth who were verbally abused in school were likely to experience symptoms of depression, anxiety, and sleep disturbances. Similarly, reports by GLSEN show associations between severe victimization and lower self-esteem as well as higher levels of depression (Kosciw et al., 2012, 2013). Other research shows that depression and suicidal feelings were low for all students, regardless of sexual orientation, when they attended a school with a positive climate (Birkett et al., 2009).

Although more attention has focused on the link between homophobia and bullying at school and compromised mental and behavioral health, some studies have examined links with education attainment and academic outcomes. There is evidence to suggest an association between bias-based harassment and academic achievement or grade-point average (Kosciw et al., 2012, 2013; Russell et al., 2001). Victimization and feeling unsafe and unwelcome in schools can also lead to missing school and negative attitudes toward school (Espelage et al., 2008; Kosciw et al., 2012; Birkett et al., 2009).

Finally, recent studies have begun to document the impact of discriminatory bullying in comparison to bullying that is not due to discrimination or prejudice. This growing body of

evidence shows that bias-based or discriminatory bullying is particularly undermining of adolescent health. Boys who are bullied based on perceived sexual orientation report higher anxiety and depression and more frequent verbal and physical bullying than boys who are bullied for other reasons (Swearer et al., 2008). In a Brazilian sample, victimization in schools was related to lower commitment to school, and this association was stronger for homophobic compared to nonhomophobic victimization (Alexander et al., 2011). Additionally, Sinclair and colleagues (2012) demonstrated that compared to general harassment, adolescents who were victims of bias-based harassment were at significantly higher risk for negative mental health outcomes, such as depression, physical self-harm, and suicidal ideation and attempts. The same study showed that the link between discriminatory bullying and negative health and behavior outcomes was magnified for youth who also reported cyberbullying. Given the increasing use of mobile technologies and social media by youth, these results raise concern about the intersection of cyberbullying and discriminatory attitudes and prejudice.

School Climate

Although school climate has been found to be overwhelmingly negative for many LGBTQ students, school cultures and educational contexts vary: Some schools are safer and more supportive of LGBTQ students than others. There is a growing body of work that focuses on the structural conditions of schools and how policies and programs can change the experiences of LGBTQ students (Russell et al., 2010). With this focus, an increasing number of policies, programs, and practices are being introduced to promote a positive school environment for all students. In addition there is growing attention (including policy attention) to curriculum that is inclusive of LGBTQ people and issues. Finally, school clubs such as GSAs have emerged as an important setting for positive development and support for LGBTQ students, and for creating positive school climates.

National and State-Level Laws

At this time there are no nationwide protections in place for LGBTQ students in the United States. Both the Student Non-Discrimination Act, introduced in the 111th session of Congress, and the Safe Schools Improvement Act, introduced in the 112th session of Congress, did not pass beyond the committee level. The proposed legislation aimed to protect LGBT students against bullying and discrimination in schools. Although there are no national protections for LGBT students, many states (as well as the District of Columbia) have laws prohibiting discrimination in schools based on sexual orientation (GLSEN, 2013). Of those states, more than a dozen have fully enumerated antibullying laws which ban harassment of students based on sexual orientation and gender identity (although nearly all of such laws to date are regarded as 'unfunded mandates' that provide no specific provision for capacity for enforcement; Russell et al., 2010).

In addition to enacting protective policies, a central issue in promoting a positive school climate is making students, teachers, and school officials fully aware of existing inclusive school policies: Students must be aware of and understand policies and how these policies affect them (Russell et al., 2010). Sandfort and colleagues (2010) found that when schools had consistent and clear rules and expectations, Dutch students with and without same-sex attraction did not differ in mental health outcomes. Further, teachers and administrators must fully understand existing policies and implement them when necessary; studies have shown that teacher support and intervention in harassment is strongly linked to students' perceptions of school safety for LGBTQ students (Russell et al., 2010).

Inclusive Curriculum

In addition to the support they provide, educators can also shape school climate with the material that they teach. Including material on LGBTQ history or on LGBTQ individuals who have influenced the fields of math, science, and literature can contribute to an inclusive environment in which students can feel less isolated and more empowered. Students identified an LGBTQ-inclusive curriculum as a strategy to promote positive school climate (Burdge et al., 2013): The *Implementing Lessons That Matter* report notes that school climate surveys conducted in schools that included an LGBTQ-inclusive curriculum showed greater feelings of safety and perceived support for LGBTQ individuals. Additionally, inclusive curriculum may help promote academic engagement in LGBTQ youth, as it is associated with higher student achievement (Kosciw et al., 2013). This study also found that it may be a moderating factor for the association between harassment and self-esteem, particularly for students in poorer school climates with worse harassment. Although positive associations were found from this inclusive curriculum, students did note that it was rare; most schools that did offer this curriculum did not include it across the school curriculum.

Gay-Straight Alliances

Along with inclusive school-level policies and curricula, GSAs may also positively impact a school's climate. These student-led clubs had their roots in early efforts to provide counseling and support to LGBT students in schools, and emerged as youth-led clubs in the northeast and west coast during the 1990s; by the mid-2000s it was clear that GSAs represented a national movement (Herdt et al., 2007). GSAs create a sense of community for LGBT students and their allies. Often, these clubs advocate for education of issues facing LGBT students among the school community. GSAs have been shown to create a safe space for students in schools; schools that include a GSA have been found to have decreased rates of victimization and greater feelings of safety and school connectedness (Goodenow et al., 2006; Kosciw et al., 2013). In a population-based sample of high school students, GSAs were associated with lower truancy, smoking, drinking, and suicidal ideation and attempts for both LGBTQ and heterosexual youth, though these associations were stronger for LGBTQ youth (Poteat et al., 2012). Important to consider, however, are the different ways that GSAs are associated with youth outcomes. A study by Toomey and colleagues (2011) found that

although the presence of a GSA in a high school was associated with higher well-being and educational attainment, GSA participation was not associated with lower negative outcomes or higher positive outcomes. However, higher perceived GSA effectiveness was associated with higher educational attainment and lower depression and substance abuse problems. This implies that it is the salience of GSAs and their perceived effectiveness in changing school environments that promotes the most positive outcomes for LGBTQ youth, regardless of individual student participation.

Conclusion

Implications for Research

Research on GSAs, policies for youth, and inclusive curriculum have contributed to a growing body of evidence on how best to create positive school climates for LGBTQ youth, yet there is still much more to be done. There is a dearth of interventions in the school environment that address the issues discussed, and even less research testing the programs, strategies, and interventions that do exist. It is crucial that interventions addressing bullying, mental and physical health, sexual education, and other important LGBTQ concerns are devised, implemented, and evaluated within the school environment. Additionally, our knowledge of the experiences of ethnic and racial minority LGBTQ adolescents is limited and much research in this area is necessary to understanding the school environment for all LGBTQ adolescents.

Implications for Schools, Parents, and Students

There are a number of ways in which to promote a positive school climate for all students. Advocating for national policy to protect students from discrimination and harassment based on sexual orientation and gender expression is paramount. Until such a policy is enacted, state laws continue to be crucial, and the nature of those laws must be disseminated to students and teachers.

Teachers are an especially important support for LGBTQ students. Professional development programs like *The Reduction of Stigma in Schools* program (Payne and Smith, 2011) can provide teachers with the information they need to support students and intervene as necessary when harassment occurs. Additionally, training teachers to implement inclusive curriculum can lead to safer schools for all students. At this time, however, these strategies are not typically requirements in schools of education and other teacher training programs. Many new and current teachers are unaware of LGBTQ issues and ways to support their students. It is imperative that classroom strategies to promote respect for all students are integrated into teacher and school administrator training and professional development programs.

Abstract

School improvement is an innovation or planned change with specific means and specific goals. There are many and diverse improvements in the paper projects but the relation between the strategies and the outcomes of student learning is difficult to answer. The merging of educational effectiveness research, which concentrates on the relation between causes and effects in education, and school improvement, which emphasizes how this knowledge can be used, can result in theory-driven and evidence-based approaches to school improvement. The article presents and discusses successful examples of this recent development in school improvement.

School improvement is an innovation or planned change with specific means (a change in learning and other internal conditions of the school) and specific goals (to accomplish educational goals more effectively). There is a wide variety of improvement efforts, which more or less meet the elements of the definition, some enhancing student outcomes, others more directed toward the professional development of teachers, toward restructuring the organization of the school, or toward improving the relationship between schools and their clients (Creemers and Kyriakides, 2012). Because of systematic evaluation of most school improvement efforts, questions about the relationship between improvement strategies, the technicalities and outcomes of improvement – ultimately students' learning outcomes – cannot be answered. A major contribution to establishing cause–effect and/or means–ends relationships in school improvement is the merging of school improvement and school effectiveness. School effectiveness can provide a knowledge base about 'what works' and 'why' in education; school improvement provides understanding of 'how' that knowledge can be introduced in educational practice. This merging of school effectiveness and school improvement has resulted in some successful projects, and the formulation of principles and conditions for effective school improvement.

School Improvement

Different terms are used to describe change processes in schools and educational systems as a whole. They include 'educational change,' 'innovation,' 'reform,' and 'development.' These terms are quite often used in an interchangeable manner, and their meaning in the literature is frequently ambiguous. Many authors do not define them, but instead tend to trust everyday usage to convey the meaning of the words. Other authors define the concept by including in the definition important conditions and crucial characteristics of the processes.

In the definition of these different concepts generally, and to distinguish school improvement from other concepts, at least three points should be taken into consideration.

1. The level in the educational system where the change takes place: the school, the district, or the state. Ultimately, every change process has to reach the classroom and the level of the individual student. In order to make a distinction, educational change at the national level is often called 'systemic reform.' The term 'school improvement' makes it clear that the change takes place at the school level.
2. In all definitions, distinctions should be made between the process of educational change (i.e., the strategies used and the characteristics of the change process) and the outcomes of the change process. In everyday use, the term can refer to one of these aspects or even to a combination of them, for example, to strategy and the product of change. Fullan clarifies what he calls "the confusion between the terms *change* and *progress*" (Fullan, 1991, p. 4). Not every change is progress: the actual outcome of the change processes in terms of progress is not as important as the intended outcomes in the desired direction.
3. When it comes to the outcomes of change, there is often no well-defined concept of what the change is aimed at: the context of education, the inputs and processes, or, ultimately, the outcomes in terms of student achievement.

The International School Improvement Project defines school improvement as a systematic sustained effort aimed at change in learning conditions and other related internal conditions in one or more schools, with the ultimate aim of accomplishing educational goals more effectively (Van Velzen et al., 1985). This definition specifies improvement as an innovation or planned change with specific means (change in learning and other internal conditions of the school) and specific goals (ultimately to accomplish educational goals more effectively).

Practice and Theory in School Improvement

School improvement as a process has been demarcated into three global phases: the initiation, the implementation, and the continuation processes. Stakeholders of school improvement are more narrowly circumscribed and consist of students, teachers, principals, and parents at the school level, and of local educational authorities, consultants, and the local community at the local level. In exceptional cases, where it is a regional or national strategy to improve all schools, the stakeholders at these levels are also relevant.

School improvement is a very widespread phenomenon and a wide variety of improvement efforts can be found. For example, there is a lot of improvement going on which does not aim at enhancing student outcomes at all. These types of improvement focus, for instance, on the career development of teachers, on restructuring the organization of the school, on the way decisions are made, or on the relationships between schools and their clients. Sometimes restructuring takes place at the classroom level. Changes in the writing practices of elementary schoolteachers, for example, have been described in great detail. Nevertheless, the actual impact of the changes on students and on student achievement is usually left out.

Some schools practice improvement on their own and try to find their own solutions to their problems. Other schools have chosen to implement as accurately as possible improvement programs that have been developed elsewhere. This is called fidelity implementation. Often they do not consider alternative educational options. For example, they may opt for a specific program primarily because another school was satisfied with it (Stringfield, 1995). Some schools are involved in improvement only because their government expects them to be (Hopkins et al., 1994). Depending on the extent to which educational policies are translated into clear outlines and contents, fidelity implementation is a more or less appropriate concept. When the educational policy is rather prescriptive with respect to curricular content and outcome levels, as it is in the UK (Hopkins et al., 1994), it is theoretically possible to check whether or not schools are implementing this policy. When the educational policy is rather open-ended, as is the Dutch policy on educational priorities (Van der Werf, 1995) or the Dutch inclusion policy, it is virtually impossible to apply the notion of fidelity implementation.

Only a small part of school improvement is based on research (Stringfield, 1995). Innovations are hardly ever tested before they are implemented in educational practice, and an adequate *evaluation* of their impact is rare. The same applies to the occurrence of experimental or quasiexperimental designs in improvement projects. Some school improvers have preferred forms of action research instead of research-based experiments. Sometimes projects based on changing only a couple of factors report great successes. It may be that changes in just a few important areas can alter a whole system, but the question is whether these changes – often cases of educational mass hysteria – will stand the test of time. In education, the margins for change are generally small, because of the impact of noneducational factors such as the individual characteristics of students.

Evaluations are often not carried out satisfactorily or are performed after a time span that is too short. Because of inadequate evaluations, questions about the causation of effects, extremely important for the school effectiveness knowledge base, cannot be answered. School improvement, therefore, should consistently pursue assessment of its results, pay attention to its failures and try to learn from these, and limit its goals to prevent confusion of cause and effect (Hopkins et al., 1999).

In school improvement, the orientation toward educational practice and policy-making is emphasized. Although in educational practice schools and classrooms can be found that succeed much better than others, theories cannot be based on exemplary practice only. Insofar as theoretical notions have been developed, they have not yet been empirically and systematically tested. The typologies of school cultures (Hargreaves, 1995), for example, have not been studied in educational practice and their effects on the success of school improvement are as yet unknown. Moreover, their relationships to the first criterion for school improvement (enhancing student outcomes) are not always very clear. The same holds for the factors that are supposed to be important in different stages of educational change, outlined by Fullan (1991) and for his ideas about the essential elements in educational change at the classroom level (beliefs, curriculum materials, and teaching approaches). Even though these ideas are derived from school improvement practice, their importance and their potential effects are not accounted for in detail, and have not yet been studied in research.

A contribution to theory development is the generic framework for school improvement provided by Hopkins (1996). In this framework, three major components are depicted: educational givens, a strategic dimension, and a capacity-building dimension. Educational givens cannot be changed easily. Givens can be external to the school (such as an external impetus for change) and internal (such as the school's background, organization, and values). The strategic dimension refers to the competency of a school to set its priorities for further development, to define student learning goals and teacher development, and to choose a strategy to achieve these goals successfully. The capacity-building dimension refers to the need to focus on conditions for classroom practice and for school development during the various stages of improvement. Finally, the school culture has a central place in the framework. Changes in the school culture will support teaching–learning processes which will, in turn, improve student outcomes (Hopkins, 1996).

Despite the obvious gaps in theory development and testing in the field of school improvement, there are already some elements of a knowledge base. By trying to improve schools, knowledge on the implementation of classroom and school effectiveness factors in educational practice has become available. This has provided the possibility of studying, to different degrees, the influence of factors and variables on educational outcomes (Stoll and Fink, 1994).

The Link between School Improvement and School Effectiveness

School effectiveness and school improvement conjoin because of their mutual interest, although their actual relationship may be very complicated (Creemers and Reezigt, 1997; Reynolds et al., 1993). The major aim in the field of school effectiveness was always to link theory and research on the one hand, and practice and policy-making on the other. School improvement can be fostered by a knowledge base covering what works in education that can be applied in educational practice. The combination of theory, research, and development is not new in education. Almost all movements start out to make knowledge useful for educational practice and policy-making, or state their goal in terms of supplementing policy practice with a knowledge base supplied by theory and research

from a cyclical point of view. The next step is to use practical knowledge for further advances in theory and research. In this way, research and improvement can have a relationship as a surplus benefit for both.

School effectiveness has led to major shifts in educational policy in many countries by emphasizing the accountability of schools and the responsibility of educators to provide all children with opportunities for high achievement, thereby enhancing the need for school improvement (Mortimore, 1991). School effectiveness has pointed to the need for school improvement, in particular by focusing on alterable school factors. School improvement projects were necessary to find out how schools could become more effective. These projects were often supposed to implement effective school factors in educational practice (Scheerens and Bosker, 1997) and, in doing so, could yield useful feedback for school effectiveness. School improvement might point to inaccurate conceptions of effectiveness, such as the notion of linearity or one-dimensionality (Hargreaves, 1995). In addition, school improvement might give more insight into the strategies for changing schools successfully in the direction of effectiveness.

The relatively short history of school effectiveness and improvement shows some successes of this linkage. Research results are being used in educational practice, sometimes with good results. School improvement findings are sometimes used as input for new research. Renihan and Renihan state that "the effective schools research has paid off, if for no other reason than that it has been the catalyst for school improvement efforts" (Renihan and Renihan, 1989, p. 365).

Most authors, however, are more skeptical (Reynolds et al., 1993). Fullan states that school effectiveness "has mostly focused on narrow educational goals, and the research itself tells us almost nothing about how an effective school got that way and if it stayed effective" (Fullan, 1991, p. 22). Stoll and Fink (1992) think that school effectiveness should have done more to make clear how schools can become effective. According to Mortimore (1991), a lot of improvement efforts have failed because research results were not translated adequately into guidelines for educational practice. Changes were sometimes forced upon a school, and when the results were disappointing the principals and teachers were blamed. Teddlie and Roberts (1993) suggest that effectiveness and improvement representatives do not cooperate automatically, but tend to see each other as competitors. Links between school effectiveness and school improvement were stronger in some countries than in others (Reynolds, 1996). Reynolds et al. (2000) came to the conclusion based on the analyses of Dutch, British, and North American initiatives that the following principles are fundamental to a successful merger of school effectiveness and school improvement:

1. a focus on teaching, learning, and the classroom level,
2. use of data for decision-making,
3. a focus on pupil outcomes,
4. addressing schools' internal conditions,
5. enhanced consistency (through implementation of 'reliable' programs), and
6. pulling levers to affect all levels, both within and beyond the school.

Recently, these elements were taken into account in developing a project aiming to use the knowledge base of school effectiveness research to develop school improvement initiatives, namely the high reliability project, and some evidence illustrating the impact of this approach to student achievement gains has been provided (Kyriakides and Christoforou, 2011; Reynolds, 2011).

In addition, an evidence-based and theory-driven approach to school improvement has been developed (Creemers and Kyriakides, 2012). This approach makes use of the dynamic model of educational effectiveness (Creemers and Kyriakides, 2008) which was developed in order to address some of the weaknesses of integrated models of educational effectiveness developed in the 1990s especially since these models do not take into account the dynamic character of educational effectiveness. The dynamic model is multilevel in nature and refers to factors operating at four different levels: student, classroom, school, and system. Changes in the functioning of school factors were found to be associated with changes in the effectiveness status of schools (Creemers and Kyriakides, 2010). Thus, school improvement projects are expected to refer to these factors. It is also claimed that factors are interrelated and thereby comprehensive strategies of school improvement addressing grouping of factors can be developed. Finally, five dimensions are used to measure the functioning of each factor and these can be used for generating constructive feedback to schools on both quantitative and qualitative characteristics of school factors (Kyriakides and Creemers, 2008).

A distinctive feature of the dynamic model is that it does not only refer to factors that are important for explaining variation in educational effectiveness but it also attempts to explain why these factors are important by integrating different theoretical orientations to effectiveness (Sammons, 2009). In this way, teachers and other school stakeholders involved in improvement efforts are offered the opportunity to use in a flexible way the knowledge base of school effectiveness research, adapt it to their specific needs, and develop their own strategies for school improvement. Thus, a dynamic approach to school improvement (DASI) has recently been developed (Creemers and Kyriakides, 2012). The dynamic model is used as the theoretical framework of this approach and a significant role to school self-evaluation for identifying improvement priorities is given. In addition, the advisory and research team (A&RTeam) has an important role to play since it is expected to support school stakeholders in their attempt to develop and implement their strategies and action plans for school improvement.

More specifically, school stakeholders and the A&RTeam should first of all define the general aim of the school improvement intervention by taking into account that promotion of student learning must be the ultimate aim of any school improvement effort. At the second step, the dynamic model and its factors are presented to the school stakeholders. This presentation will help them understand how and why by addressing the school factors student learning can be promoted. At the third step, schools should develop their own school self-evaluation mechanisms in order to collect and analyze data about the functioning of school factors and identify their priority area(s) for improvement. The fourth step is one of the most important steps of DASI. The A&RTeam should work closely with the

school stakeholders in order to help them define their strategies and action plans for improvement. School stakeholders are expected to take into account the available knowledge base of educational effectiveness research and adopt the guidelines emerging from the literature on their school context (with the help of the A&RTeam). Then school stakeholders and the A&RTeam should develop mechanisms for monitoring the implementation of the intervention. At this point, DASI gives emphasis to the role of formative evaluation and the importance of using evaluation data to further develop the school improvement strategies and action plans. Finally, the A&RTeam and the school stakeholders should develop summative evaluation mechanisms in order to measure the impact of DASI on promoting student learning. This step will not only help school stakeholders test the theory upon which their intervention is based but may also reveal the importance of identifying a new priority area for improvement. If summative evaluation reveals that a school has managed to substantially improve the functioning of the factor(s) addressed, school stakeholders and the A&RTeam may decide to collect new evaluation data and identify a new priority improvement area. By conducting school self-evaluation a new priority area will be identified and a new improvement project will be developed. It can therefore be claimed that DASI is based on the assumption that effective schools always search for ways to improve further their effectiveness status.

In order to demonstrate the development and use of DASI in educational practice, projects showing the conditions and methods with which the proposed approach can be used for school and teacher improvement have been undertaken (Antoniou and Kyriakides, 2011; Bren et al., 2012). These projects address important challenges which many schools in different countries face, such as establishing school self-evaluation mechanisms, facing and reducing bullying, improving assessment practices, and promoting teacher professional development. It was shown in these studies that the DASI approach helped participating schools to develop their own strategies and actions for improvement, in relation to specific challenges they faced, and also assisted in the improvement of their effectiveness status as this was measured through student achievement in different learning outcomes.

During the last decade, we have different approaches to school improvement that are based on the knowledge base of educational effectiveness research (Hallinger and Heck, 2011; Houtveen and van de Grift, 2012; Mongon and Chapman, 2012; Muijs et al., 2011). Some projects investigating the extent to which these approaches can be used in practice have been undertaken. Further research is needed to compare the elements of these approaches and their impact on student learning outcomes. In this way, a more comprehensive approach to school improvement which will be based on a theory of effective education and will be able to promote quality and equity in education could be developed.

School Learning for Transfer

Gavriel Salomon, Haifa University, Haifa, Israel

Abstract

Most of what is taught in school is expected to affect learning and performance that transcend the mastery of those subjects. Such transfer from A to B is likely to occur when more elements are common to both or when one acquires a general principle that can be transferred to new instances. However, there is a great discrepancy between the expectation for transfer from school learning to the acquisition of new subjects and the handling of daily events where transfer appears more frequently. According to one theory, transfer takes place either through automatic application of well-rehearsed knowledge ('low road') or through mindful processes of abstraction. Often, neither road is taken and thus transfer fails. Recent developments challenge the basic paradigm and conception of transfer, suggesting for example to focus on transfer as 'preparation for future learning,' or seeing learning as a matter of participation in a community of learners in an active process of *knowing-as-construction within a social context of activity*. Some suggest a *detect–elect–connect* model, while others offer a more *expansive framing* that emphasize the future uses of learned content. Transfer can be facilitated by reflective abstraction (high road), practice to near automaticity (low road), emphasis on significance and potential diverse uses (expansive versus bounded framing), and fostering seeing through the surface to deeper structure.

Most of what is taught in school is expected to affect learning and performance that transcend the mastery of those subjects: one learns addition to prepare the grounds for the study of multiplication, science to understand the surrounding physical and natural world, and history to gain a sense of identity and a deeper understanding of current events. Such expectations concern the transfer of what is learned in school in one domain to other realms of learning and activity in school and beyond, a spillover of learning that functions like a ripple effect. Thus, the study of topic A is supposed to facilitate learning of and/or performance on B, a later topic or activity often of a very different nature and in a different context. The prior study of A makes B easier, faster, or better understood relative to B without the learning of A preceding it.

Sometimes a prior A may interfere with B; this is generally called negative transfer, as when having mastered driving a car interferes with steering a semitrailer truck in reverse, a theme not pursued further here. Also, the current literature recognizes complex interactions between A and B. In facing situation B and drawing on A to deal with it, the learner may reconstruct A to some extent and thereby learn more about A, for instance broadening its meaning or identifying variants (e.g., Cook, 2003; Ross and Kennedy, 1990).

Transfer has been of special interest to researchers and educators because of many findings of failure to transfer – school learning of A not having the spillover effects hoped for to B. Some have held that the prospects for transfer markedly beyond what is most immediately and specifically learned are intrinsically poor. Educational aspirations and planning should take this into account. However, the prospects for transfer are contentious, a theme developed further below.

Two Basic Approaches

Two approaches to the study of transfer have dominated the field since the beginning of the twentieth century: transfer as a function of similar elements between A and B, and as a function of the understanding of general principles drawn from A (and perhaps other context) that are transferable to a variety of situations including B. The history of research on transfer shows how these two major principles underlie the development of the field, even when other basic assumptions about learning and thinking have recently been challenged.

The expectation for transfer has as long a history as institutional learning itself. Plato argued that the study of abstract reasoning assists the solution of daily problems. Similarly, the debates about Talmudic and Biblical texts in ancient times were argued to 'sharpen minds.' The scientific study of transfer has a long history as well; it dates back to the beginning of the twentieth century with the studies by Thorndike and Woodworth (1901) in which the idea that Latin and other taxing school subjects developed one's general 'faculties of mind' was challenged. The expected transfer was not found; mastery of Latin, Greek, or geometry did not facilitate either performance or efficiency in learning other subjects. Thorndike's School Improvement findings led to his formulation of the theory of 'identical elements': transfer from A to B is likely to occur when more elements are common to both. It followed that transfer can take place only in the relatively rare case when there is clear and apparent similarity between the constituent elements of the learned topics. Thus, one would have to learn a host of independent issues and procedures as no transfer in the absence of identical elements should be expected.

Thorndike's theory was countered by a more cognitively oriented and Gestalt-flavored alternative that emphasized the meaningful conceptual understanding of underlying principles, which then could be thoughtfully applied to new situations. The more general the learned principle, the farther could it be transferred to new instances. Judd (1908) had his subjects learn to shoot at targets submerged in water after having learned principles of light refraction in water. Having learned these principles, subjects were much better at hitting the targets than those who have only practiced the activity.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92040-3

As we shall see below, the two approaches – transfer as a matter of common elements and transfer as a matter of higher-order cognitive processes of understanding and abstraction – although having undergone profound modifications and developments over the years, continue to this day to dominate the field.

Transfer Missing in Action

The history of research on transfer as well as practitioners' expectations for transfer might be characterized as an ongoing pendulum-like oscillation between the two approaches. One of the hallmarks of the field is the great discrepancy between the expectation for transfer from school learning to the acquisition of new subjects or to the handling of daily events and the findings from controlled transfer studies. The latter often do not yield evidence of the hoped-for transfer. A typical case comes out of research on children learning programming, which some thought might develop general cognitive capabilities of various kinds. Pea and Kurland (1984) found, contrary to expectations, that children learning LOGO programming showed no advantage in their ability to plan over children who did not master LOGO.

Transfer, when at all found in carefully carried out studies, appears to be highly specific, as when a particular procedure or principle is applied in a new situation which bears great and apparent (often analogical) similarity to the learning material, and when the process is accompanied by such facilitation as coaching, specific guidance, and cueing (see Bransford and Schwartz, 1999; Cox, 1997, for detailed reviews). Such findings would seem to support Thorndike's theory and pessimism about transfer, as summarized by Detterman (1993): "In short, from studies that claim to show transfer and that don't show transfer, there is no evidence to contradict Thorndike's general conclusions: Transfer is rare, and its likelihood of occurrence is directly related to the similarity between the two situations" (p. 15).

There is a notable anomaly here, however. Whatever the pattern of findings from formal studies, it is apparent that in everyday life a great deal of transfer occurs unproblematically (Bereiter, 1995). People readily understand metaphors, jokes, and explanatory analogies, all of which are based on the transfer of ideas from elsewhere – and often construct them on the fly – even though these commonly require connecting two very different conceptual domains. People routinely learn skills and stretch them to other contexts, as in knowing how to drive a car and readily driving a rented moving van. People acquire robust skills such as reading and apply them in diverse contexts. Transfer of certain sorts in certain settings is so plentiful that plainly there is more to understand about when transfer succeeds or fails and why.

Transfer on the Rebound

While Thorndike's pessimism seemed to have won the day for a while, the research tradition of Judd (1908), with its emphasis on comprehension and general (nonspecific) transfer gradually showed its strength. As research of this tradition tended to show, when relevant principles or strategies are mindfully attended to, or better yet – either abstracted by learners and/or metacognitively monitored – transfer to a variety of instances can be obtained even in the absence of apparent common elements.

At the same time, other research on the transfer of skills, ostensibly still in a tradition more similar to that originated by Thorndike (Thorndike and Woodworth, 1901), has also yielded positive results. Thus, for example, Singley and Anderson (1989) have shown that when training to near automaticity of discrete skill components is carried out, transfer from one task (e.g., a line editor) to another (text editor) can be virtually perfect. Also more field-based research found support for impressive transfer from the study of university-taught disciplines: Nisbett et al. (1993) have shown that the study of psychology, and also to a lesser extent medicine (but not law or chemistry), improves students' abilities to apply statistical and methodological rules of inference to both scientific and daily problems.

Such positive cases of transfer of learning stand in contrast to the many seeming cases of failure to transfer. How might the discrepancy be understood? Chi (in press) notes that failure to transfer has often been explained by shallow initial learning. In such circumstances, one still might speak of failure to transfer, albeit from impoverished initial learning. However, arguably, such cases are not best viewed as failure to transfer but simply as failure to achieve reasonably robust learning as a basis for transfer. This notion is developed in the following section.

The High and the Low Roads to Transfer

The renewed success of the two lines of research, often addressing higher-order cognitions and information processing exercised by multiple activities, suggests that transfer may not be a unitary process as the two approaches differ in important ways. Observing these differences, Salomon and Perkins (1989) have developed a theory to account for the possibility that transfer takes either one of two routes (or a combination thereof), described as the *high road* and the *low road* of transfer.

The low road reflects to an extent the Thorndikian line, and more recently that of the Singley and Anderson (1989) skill-acquisition and transfer theory. It is taken when skills, behaviors, or action tendencies are repeatedly practiced in a variety of situations until they are mastered to near automaticity and are quite effortlessly applied to situations whose resemblance to the learning situations is apparent and easily perceived (e.g., reading and driving). In this respect, transfer is not based on the development of abstract mental representations, "but through the incremental refinement of knowledge resources that account for – rather than overlook – contextual variation" (p. 1). Transfer is thus constructed piece by piece (Wagner, 2006). Other candidates for low-road transfer are attitudes, cognitive styles, dispositions, and belief systems, the application of which to new situations is rarely a mindful process.

In contrast, the high road to transfer is characterized by the process of mindful abstraction of knowledge elements that afford logical abstraction: principles, rules, concepts, procedures, and the like. It is this mindfully abstracted, decontextualized idea ('ethnic oppression may lead to revolt') that

becomes a candidate for transfer from one particular instance (the Austro-Hungarian Empire) to another (Russia and Cechenia). Simon (1980) commented in this respect that "To secure substantial transfer of skill acquired in the environment of one task, learners need to be made explicitly aware of these skills, *abstracted from their specific task content*" (p. 82, emphasis added).

There is ample evidence to support the role of the high road in obtaining transfer. One of the studies by Gick and Holyoak (1983) illustrates this point. Participants who were given two stories and were asked to write a summary of how the two stories resembled each other (i.e., their common moral) showed a 91% transfer to the solution of another story, relative to 30% transfer of a nonsummary group. Bassok (1990) showed that mastering algebraic abstractions (plus examples) allowed students to view physics problems as particular instances to which the more abstract algebraic operations could be applied. Physics, on the other hand, is too particular and thus students do not expect and do not recognize any possible relationship between it and algebraic operations. Research also directs attention to the role played by self-regulation and metacognitions in the process of mindful abstraction and transfer via the high road. Following the studies and review of Campione et al. (1982), Salomon et al. (1989) have shown that students interacting with a semi-intelligent computerized Reading Partner that provides metacognitive-like guidance tend to internalize that guidance and transfer it to new reading as well as to writing situations.

The high road–low road theory sheds light on the many failures of obtaining transfer in controlled studies. Close examination of such studies suggests that in many cases neither the low road of repeated practice nor the high road of mindful abstraction was taken. Not enough time is allocated for practice for the former, and not enough attention is given for mindful abstraction for the latter. As a consequence, neither near automatic transfer on the basis of easily recognized common elements, nor farther transfer on the basis of metacognitively guided mindful abstraction can be attained.

New Approaches

Research on transfer, until recently, did not challenge the basic paradigm and conception of transfer as a process involving change of one's performance on a new task as a result of his or her prior performance on a preceding and different task. Such a conception of transfer has recently become challenged on the basis of new theories of learning, the role of activity, and the place of cognitions therein. These challenges can be arranged along a dimension ranging from the least to the more radical, relative to traditional notions of transfer.

Bransford and Schwartz (1999), coming from a mainstream tradition of cognitive science applied to instructional issues, argue that the current ways of demonstrating transfer are more appropriate for studying only full-blown expertise. According to them, "There are no opportunities for…[students] to demonstrate their abilities to learn to solve new problems by seeking help from other resources such as text or colleagues or by trying things out, receiving feedback, and getting opportunities to revise" (p. 68). They recommend replacing the typical transfer task which they call 'sequestered problem solving' (SPS) by a conception of transfer as 'preparation for future learning' (PFL). Thus, one would measure transfer not by having students apply previously acquired knowledge or skill to new situations, demonstrating either *knowledge how* or *knowledge that* something, but rather by demonstrating *knowledge with* – thinking, perceiving, and judging with whatever knowledge and tools are available even if that knowledge is not consciously recalled. In other words, transfer would be expected to become demonstrated by way of 'people's abilities to learn new information and relate their learning to previous experiences' (Bransford and Schwartz (1999: 69).

An illustration of the above can be seen in a study in which college and fifth-grade students did not differ in their utilization of previous knowledge and educational experiences for the creation of a statewide plan to recover the bald eagle. This is a typical SPS way of measuring transfer, suggesting in this case that previous educational experiences did not transfer to the handling of the new problem. However, when the students were asked to generate questions that would need to be studied in preparation for the creation of a recovery plan (applying a PFL approach), striking differences were found between the two age groups in favor of the college students. Focusing on different issues, the two groups showed how, knowingly or not, previous learning has facilitated the generation of the list of questions to be asked. The use of tools and information resources would also show how previous learning of skills and knowledge becomes actively involved in the process of solving a new problem.

While Bransford and Schwartz (1999) continue to adhere to the traditional conception of learning as knowledge acquisition and to cognitions as general and transferable tools of the mind, others have developed an alternative, sociocultural approach according to which neither the mind and its content (e.g., arithmetic algorithms) should be treated as a neutral toolbox ready for application wherever suitable, nor should knowledge-in-use and social context of activity be taken as two independent entities. Learning is a matter of participation in a community of learners; thus knowledge is not a noun denoting *possession* but rather a verb denoting the active process of *knowing-as-construction within a social context of activity*. One underlying assumption is that learner, activity, and content become united through culturally constructed tools. A second assumption is that learning is highly situated in a particular activity context of participation, and its outcomes are 'becoming better attuned to constraints and affordances of activity systems so that the learner's contribution to the interaction is more successful' (Greeno, 1997: 12). Seen in this light, the traditional *cognitivist* concern with the transferability of acquired knowledge across tasks becomes, from the newer *situative* perspective, an issue concerned with the task and the 'consistency or inconsistency of patterns of participatory processes across situations' (Greeno, 1997: 12).

An important practical implication of this approach is that one would need to take into consideration the kinds of participatory activities to which school-based learning might be expected to transfer, rather than expect decontextualized school materials to transfer all on its own to other tasks, situations, and activities. Students are likely to restructure new situations to fit their previous practices and thus make the old available

for transfer to the new. Illustrating this approach to learning and cognition, Saxe (1991) showed that Brazilian children's mathematical experience as street vendors affected their math learning when later on they became enrolled in school, and vice versa. "[I]n recurring activities like practices of candy selling and schooling – contexts in which knowledge is well learned and in which similar problems emerge on a repeated basis – transfer is a protracted process. In their repeated efforts to solve practice-linked problems, individuals attempt to structure problem contexts in coherent and more adequate ways" (p. 179).

The theme of looking at transfer realistically in context, asking what can be expected, and examining what kinds of learning experiences might prepare learners for challenging transfers has proved persistently fruitful. For instance, Lobato (2003) has urged the importance of an *actor-oriented* perspective on transfer. She warns that studies of transfer commonly neglect what's going on with the learner. They reflect an outside or expert perspective, seeking the wide and deep transfer that would mark mastery of ideas. Lobato suggests that transfer in fact is common but takes modest forms initially, gradually building toward something broader, given further learning opportunities. Teaching and learning practices should expect and build upon this.

Chi (in press) also emphasizes how commonplace useful transfer is. Transfer comes easily when surface similarities and deep structural similarities go together, which they often do. The surface similarities cue the learner to make the deeper connections. Transfer gets tricky when surface dissimilarities mask deep structural similarities, leading learners to miss the opportunity, or when surface similarities trigger mistaken efforts to match up circumstances dissimilar under the surface. Appropriate transfer in such cases requires 'seeing through' the surface to deeper relationships. Studies of topics can be organized to cultivate this.

Relatedly, Perkins and Salomon (in press) urge understanding successes and failures of transfer according to a detect–elect–connect model. They note that treatments of transfer for the most part do not differentiate how learners *detect* possible relationships in the moment, why they *elect* to pursue them, and, if so, how successfully they build a meaningful *connection*. Any of the three can lead to failure of transfer. Imagine a student who has learned some good principles of informal negotiation. In a tense real-life situation, the student might never even think of those principles (a problem of *detect*), feel too indifferent to use them (*elect*), or have difficulty adapting them to the circumstances (*connect*). Effective teaching for transfer needs to prepare the learner for all three.

Emphasizing how classroom dynamics cultivate learner mindsets for or against transfer, Engle (2006) draws a provocative distinction between *bounded framing* and *expansive framing* of learning. In bounded framing, classroom practices treat the content to be learned as for today, for the test, to master because it's in the curriculum. In expansive framing, classroom practices emphasize the future uses of content in school and beyond, how content connects across areas, how learners can be responsible for bringing forward content from past learning and carrying content forward from today's learning, and similar themes. Engle argues that bounded versus expansive framing influences considerably what sorts of transfer occur.

The new approaches to transfer clearly deviate from the traditional views. They suggest new ways of measuring transfer, and more radically – challenge traditional assumptions by treating knowledge, skill, task, activity, and context as one participatory activity. By so doing, they emphasize the uniqueness of each activity setting. An important aspect of this approach is its ability to incorporate within the idea of participatory activity motivational and dispositional elements also. These elements have so far been neglected by much research on transfer, although they may be crucial for students' choice to treat each situation as different, or as allowing students to exercise familiar patterns of participation. Still, it appears that despite these important novelties, the principles of transfer as a function of similarity between situations (or activities) and of depth of understanding general principles (e.g., of useful participation in a community of learners) have not yet been replaced but only redefined.

The Prospects of Teaching for Transfer

Early conceptions of transfer and its teaching assumed that special strategies were not required. One taught as usual for the usual student attainments and expected substantial transfer. Abundant research has shown this optimism to be misplaced. For many kinds of content and skill, transfer to hoped-for targets turned out not to be an automatic consequence of routine school learning.

A century of research on transfer of learning has yielded a much more differentiated conception of the conditions under which various kinds of transfer are likely to occur. First of all, there are conditions of initial learning that influence the prospects of transfer: emphasis on reflective abstraction (high road), practice to near automaticity (low road), emphasis on significance and potential diverse uses (expansive versus bounded framing), fostering seeing through the surface to deeper structure, exploration of ideas before formal instruction as PFL, and so on. Classroom learning certainly can be organized to attend to such conditions. Moreover, doing so is highly synergistic with other educational goals, such as learning for understanding. Indeed, as emphasized earlier, many of the cases of seeming failure to transfer in the literature can be attributed to impoverished initial learning.

Furthermore, there are conditions for transfer that figure in moments of use – strong versus weak cuing in everyday circumstances, intrinsic or extrinsic motivation in the moment to pursue a connection, and the presence or absence of rival responses such as entrenched habits or attitudes. Classroom learning can be organized to anticipate the conditions of moments of use, for instance by alerting students to everyday clues and preparing students to deal with rival responses.

In summary, research on school learning for transfer certainly tells educators to adjust their expectations. However, it is not so much that educators need to lower their aspirations for transfer. Rather, educators need to raise their standards to styles of classroom learning supportive of transfer.

School Management

Brian J Caldwell, University of Melbourne, Melbourne, VIC, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The somewhat negative view of school management at the end of the twentieth century has given way to a more upbeat and positive account, reflecting a tighter integration of management and learning. Large-scale studies or meta-analyses of developments in different countries have led to a more nuanced approach to school management especially in high-performing systems. Significant challenges lie ahead in school management for innovation, a capacity for futures thinking, and preparation and ongoing professional development.

The article for school management in the first edition of *International Encyclopedia of the Social and Behavioral Sciences* provided a somewhat negative even depressing account of the standing of the field. 'School management is in considerable disarray, if not turmoil, and is likely to remain so in the first decade of the twenty-first century.' It argued that this was a reflection of (1) the sweeping transformations in society and their impact on schools, (2) the disjunction between educational management as a field of practice and a field of study, and (3) the weak connection between school management and learning.

An appraisal in this second edition is much more upbeat to the point that the last decade may have seen the most important advances in the study and practice of educational management since the field was established more than five decades ago. Even though the aforementioned disjunction may still be evident and the link to learning is still not as strong as it should be, the outlook for the decade ahead is more optimistic. Especially noteworthy is that developments in school management have been incorporated in a narrative of what has transpired and this is a reflection of how leading scholars who have contributed to the field over time are now able to place events in perspective. Also noteworthy is the way meta-analyses of developments in different countries have yielded dependable knowledge of approaches to successful management *for* schools and *in* schools.

There are, however, significant challenges for the decade ahead. These lie in three domains: (1) the management of innovation in schools; (2) the development of a futures perspective given the rapid changes in education, reflecting continuing sweeping changes in society; and (3) the preparation and ongoing development of those engaged in school management.

Definition of School Management

In some nations, notably the USA, administration is used to describe a range of functions performed by the most senior people in an organization, with management a more limited, sometimes routine set of tasks, often performed by those in supporting roles. The work of Kotter (1990) is helpful in resolving the issue. Leadership is concerned with change and entails the three broad processes of establishing direction, aligning people, and motivating and inspiring. Management is concerned with the achievement of outcomes, and the three broad processes of planning and budgeting, organizing and staffing, and controlling and problem solving.

There is a generally held view that the work of those who hold senior positions in schools, especially principals or headteachers, entails both leadership and management. They should certainly be leaders. In some instances, managers will support them. There is concern when they act solely as managers. Kotter (1990) offered a contingent view that is as helpful for schools as it is for organizations in general. He contends that the emphasis and balance in leadership and management are contingent on two variables: the amount of change that is required and the complexity of the operation. Complex schools in a turbulent environment require high levels of leadership and management. Schools that are relatively simple in size and structure but are faced with major change require leadership more than management. Schools that are complex in stable circumstances require management more than leadership. Relatively simple schools in stable settings may require little of each.

School Management as a Field of Practice

The three developments described in the first edition are even more evident at the start of the second decade of the twenty-first century: (1) the shift of authority and responsibility to schools in systems of public education within centrally determined frameworks of curriculum, standards, and accountabilities (school autonomy, school-based management, local management, or self-management); (2) higher expectations for schools as governments realize that the knowledge and skill of their people are now the chief resource if nations are to succeed in a global economy; and (3) change in the nature of schooling itself, driven to a large extent by advances in information and communications technology so that much of the learning that in the past could only occur in the classroom can now occur at anytime and anywhere there is access to a networked computer.

School Management as a Field of Study

School management has emerged relatively recently as a subfield of study within the broader field of educational

management (administration). There were few formal programs and little research on the phenomenon until the 1950s. Prior to that, approaches to the management of schools paralleled those in the industry. Departments of educational administration made their appearance in universities in the US in the mid-twentieth century and soon proliferated. They were established in the UK soon after, with many other nations following suit, drawing on the US and, to a lesser extent, the UK for their intellectual underpinnings. The first quarter-century, from the early 1950s to about the mid-1970s, was characterized by efforts to build theory in educational management, modeling to a large degree the discipline approach of the behavioral sciences. In the USA, *Educational Administration Quarterly* was an attempt to provide for education what *Administrative Science Quarterly* had done for administration (management). Separate subdisciplines were created in fields such as economics, finance, governance, human relations, industrial relations, law, planning, policy, and politics.

The theory movement in educational management was the subject of powerful attack in the mid-1970s, notably by the Canadian scholar T.B. Greenfield (1975). The critique was largely directed at efforts to build a scientific theory of educational management; the separation of management from learning and teaching; and fundamental considerations of context, culture, ethics, meaning, and values.

On a more pragmatic level, the critique of educational management as a field of study referred to its failure to impact practice on a large scale and to assist in a timely manner the implementation of reform and the resolution of concerns. A promising approach to unifying the field was to place learning at the heart of the effort. This means that policy interest in the improvement of student outcomes should be the driver of this 'quest for a center,' as the US scholar Joseph Murphy (1999) described it.

Much momentum was gained in the 1990s with the establishment of the International Congress for School Effectiveness and Improvement, which made its mission the bringing together of policymakers, practitioners, and researchers. *School Effectiveness and School Improvement* quickly established itself as a leading international journal.

Extending the Narrative

A narrative is important to give a sense of coherence and continuity to what at first sight may be a series of relatively disconnected or fragmented events. Strategic intentions can be communicated through a narrative in ways that detailed plans and policies often miss. Commitment and support can be marshaled if there is an attractive and credible narrative.

Murphy (1999) placed developments to the end of the twentieth century in a narrative starting from 1820 and continuing to the end of the twentieth century. He suggested that the 'center of gravity' of educational administration (management) shifted from philosophy (1820–1900), through management (1901–45) and social sciences (1945–85) to school improvement (1986–99). The foundation moved during these time frames from religion through administrative functions and academic disciplines to education. The 'engine' changed from values through practical knowledge and theoretical knowledge to applied knowledge. The dialectic from 1986 continues to the present with a more robust consensus on this reading of developments than at the time of Murphy's account.

The narrative has been extended in recent years but in a way that reflects a stronger link between management and learning. This is illustrated in the identification by Hargreaves and Shirley (2009) of approaches to leading and managing change over more than four decades. Hargreaves has had a major interest in teaching, teacher professionalism, school leadership, and change over several decades and has offered a powerful critique of aspects of educational reform from time to time. They described four 'ways' or broad approaches to change (Hargreaves and Shirley, 2009, p. 44), the first three of which were (1) from the end of World War II to the mid-1970s characterized by innovation and inconsistency, with an 'interregnum' from the mid-1970s to the late 1980s to a situation that involved a high level of complexity and contradiction; (2) from the late 1980s to the mid-1990s with an emphasis on markets and standardization; and (3) from the late 1990s to 2009 that shifted the focus to performance and partnerships. Each of the three ways is analyzed in a number of domains including control, purpose, trust, community engagement, curriculum, teaching and learning, professionalism, professional learning communities, assessment and accountability, and lateral relations. For example, for teaching and learning, there have been different emphases over time, with developments being eclectic and uneven (first way), prescriptively driven by standards and testing (interregnum), direct instruction to meet standards and test requirements (second way), and autocratically data driven yet customized approaches (third way).

The 'fourth way' that is emerging in the second decade of the twenty-first century, and advocated by Hargreaves and Shirley, calls for the retention of aspects of the first three ways and abandonment of others. For example, moving from the third way to the fourth should see the retention of balance and inclusiveness, public involvement, financial reinvestment, better evidence and professional networks, and the abandonment of 'persistent autocracy,' imposed targets, obsession with data, and 'effervescent interactions.' There are implications for each of the four ways for school management on two dimensions: management *for* schools and management *in* schools.

While narratives along these lines are helpful, and do indeed give a sense of coherence and continuity in school management, there have been further developments since the turn of the century that suggest a more nuanced approach to description and advocacy in different settings, and these emerged from an unprecedented series of international studies, the findings of which have been synthesized through meta-analyses.

Meta-Analyses of School Management in Different International Settings

A major development in the first decade of the twenty-first century is the large-scale meta-analyses of test results and other indicators of high performance in many countries, the most prominent of which have been conducted by the Organization for Economic Cooperation and Development (OECD) and the

international consultancy McKinsey & Company. The findings and their implications for school management are summarized below.

Most systems of public education around the world have included decentralization of decision-making in their plans for school reform or restructuring. There has also been significant centralization. The OECD explained it in these terms in summarizing the findings in its annual report in 2004:

> Placing more decision-making authority at lower levels of the educational system has been a key aim in educational restructuring and systemic reform in many countries since the early 1980s. Yet, simultaneously, there have been frequent examples of strengthening the influence of central authorities in some areas.
>
> OECD, 2004, p. 34

The OECD report described the locus and mode of decision-making in four domains. Locus referred to which of six levels decisions were made: national, state, regional, municipal, local, or school. Mode referred to which of four ways decisions were made: full autonomy at the level concerned, consultation with other bodies at that level, independently but within a framework set by a higher authority, or other. The four domains were organization of instruction, personnel management, planning and structures, and resources. There have been important changes to school management as a result of these trends. While there are different patterns among the nations, it is evident that those immediately concerned with the management of schools have needed a heightened capacity in each of these domains.

Findings from analyses of test results in Program for International Student Assessment (PISA) conducted by OECD suggest that the most successful systems of schools secure an optimal balance of autonomy, accountability, and choice. A model was constructed to explain the joint impact of school and system resources, practices, and policies on student performance. Of the 15 factors in the model, the system average on the school autonomy index in budgeting is by far the most powerful (OECD, 2007). Particularly striking are two studies conducted for OECD by the Ifo Institute for Economic Research at the University of Munich (Department of Human Capital and Innovation), one focusing on the level of student achievement and the other on equity of student achievement. On level of student achievement, the following findings are striking:

> On average, students perform better if schools have autonomy to decide on staffing and to hire their own teachers, while student achievement is lower when schools have autonomy in areas with large scope for opportunistic behavior, such as formulating their own budget.
>
> Wößmann et al., 2007, p. 59

> Students perform substantially better in systems where private school operation creates choice and competition. At the same time, student achievement increases along with government funding of schools. A level playing field in terms of government funding for public and private schools proves significantly performance enhancing.
>
> Wößmann et al., 2007, pp. 59–60

As far as equity is concerned:

> [R]ather than harming disadvantaged students, accountability, autonomy, and choice are tides that lift all the boats … there is not a single case where a policy designed to introduce accountability, autonomy, or choice into schooling benefits high-SES [socio-economic status] students to the detriment of low-SES students.
>
> Schütz et al., 2007, pp. 34, 35

There is tension between these findings and the narrative offered by Hargreaves and Shirley as summarized earlier, especially with respect to competition. However, there are important implications for those concerned with school management, who are operating or may need to operate in a milieu of relatively high levels of autonomy, accountability, and choice.

Three reports of McKinsey & Company shed light on developments in school management in different countries with a particular focus on approaches associated with high performance. The first (Barber and Mourshed, 2007) drew on practice in several countries and school systems to explain how the world's 'best performing systems come out on top.' The report drew extensively on practice in Finland that had attracted headlines for its consistently high performance in PISA but also other high performers including Alberta (Canada), Australia, Belgium, Finland, Hong Kong, Japan, Netherlands, New Zealand, Ontario (Canada), Singapore, and South Korea. Jurisdictions with a strong improvement strategy included the following in the United States: Atlanta, Boston, Chicago, New York, and Ohio. The main finding was concerned with the quality of teaching, with the key themes being: getting the right people to become teachers, developing effective instructors, and ensuring every student performs well. Indicators of 'best practice' in the second theme illustrated the relevance of the study as far as school management is concerned. Key issues for this second theme are illustrated in the following, with indicators included in parentheses: coaching for new teachers (at least 20 weeks), time spent in professional development (10% of working time), role of school leaders in effective instruction (best coaches are selected as leaders), and school-based research on effective practice (research budget of USD50 per student). These findings suggest that school leaders have an important role in the management of instruction in high-performing school systems. The concept of 'talent management' has emerged in recent literature (for example, Davies and Davies, 2011).

The findings in another report of McKinsey & Company (Mourshed et al., 2010) highlighted the need for a nuanced approach to school management depending on the setting. In this instance, the study was concerned with school systems that were already high performing and were getting better and others that were starting from a low base and were showing noteworthy improvement. Examples of the former included Singapore, Hong Kong, and South Korea. The latter included Western Cape in South Africa, Minas Gerais in Brazil, and Madhya Pradesh in India. There were 18 countries in the sample (a total of 20 systems including three from the United States). The 20 systems were classified on a robust evidence base in four 'journeys': poor to fair ('achieving the basics of

literacy and numeracy'), fair to good ('getting the foundations in place'), good to great ('shaping the profession'), and great to excellent ('improving through peers and innovation'). There were three main findings:

1. It's a system thing, not a single thing: There is a common pattern in the interventions improving systems use to move from one performance stage to the next, irrespective of geography, time, or culture.
2. Prescribe adequacy, unleash greatness: There is a strong correlation between a school system's improvement journey stage and the tightness of central control over the individual schools' activities and performance.
3. Common but different: Our findings indicate that six interventions occur with equal frequency across all the improvement journeys, though manifesting differently in each one (Mourshed et al., 2010, pp. 33, 34).

The second finding ('prescribe adequacy, unleash greatness') is especially applicable for the journey from good to great wherein only loose, central guidelines for teaching and learning processes are provided 'in order to encourage peer-led creativity and innovation inside schools, the core driver for raising performance at this stage.' The 'intervention cluster' for the journey from great to excellent includes cultivating peer-led learning for teachers and principals, creating additional support mechanisms for professionals, and system-sponsored experimentation/innovation across schools (Mourshed et al., 2010, p. 36).

The report provides examples of interventions for each of the three findings. For the first finding ('it's a system thing, not a single thing'), interventions in the journey from great to excellent include collaborative practice among educators, decentralizing pedagogical rights to schools and teachers, creating rotation and secondment programs across schools and between center and schools, providing additional administrative staff, sharing innovation from the front line, and funding for innovation (p. 51). For the second finding ('prescribe adequacy, unleash greatness'), the report concluded that "lower-performing systems focus on raising the floor, while higher performing ones focus on opening up the ceiling" (p. 52). For the third finding ('common but different'), particular attention is given in the journey from great to excellent to 'attracting top talent,' with teachers' base salary significantly above per capita GDP (p. 62).

These findings reinforce the theme that there is no one best way as far as school management is concerned. Those schools starting from a low base but showing rapid improvement such as those in Brazil, India, and South Africa will focus on a different set of tasks and have different priorities than those that are high performing and getting better, as in Hong Kong, Singapore, and South Korea. School managers in the former are on a journey "characterised by lower skill educators [and] exercise tight, central control over teaching and learning processes in order to minimise the degree of variation between individual classes and across schools." School management in the latter is conducted in contexts that "provide only loose, central guidelines for teaching and learning processes, in order to encourage peer led creativity and innovation inside schools, the core driver for raising performance at this stage." As noted above in the context of the OECD studies, there is a tension in these more nuanced approaches with the 'fourth way' described and advocated by Hargreaves and Shirley (2009).

A third report of McKinsey & Company provided a sharper focus on leadership (Barber et al., n.d.). It contained a review of developments to 2010 in eight jurisdictions: Alberta (Canada), England, Netherlands, New York, New Zealand, Ontario (Canada), Singapore, and Victoria (Australia). The authors claim that "all perform strongly on international tests, or their performance in this respect is improving, and they demonstrate good practice in school leadership" (p. 4). The report drew on a literature review; interviews with experts, policymakers, and leaders in each jurisdiction; and a survey of 1850 leaders. While the broad findings and the specific illustrations stand up well to critical scrutiny, the limitations of meta-analyses on this scale are evident. For example, the claim of strong or improving performance may be challenged in the cases of England and New York, although examples of outstanding practice can be found in each system. Broad-based generalizations about policy and practice cannot be made across a jurisdiction, a point that was made well in the second McKinsey report cited above (Mourshed et al., 2010).

The report cited the view of an official in Singapore who stated that "one of the key revelations over the past ten years is that school leadership is not just an HR issue – it is a strategic issue" (p. 5). Reference was made to an analysis of practice in England that suggests that:

> [T]he overall performance of a school almost never exceeds the quality of its leadership and management. For every 100 schools that have good leadership and management, 93 will have good standards of student achievement. For every 100 schools that do not have good leadership and management, only one will have good standards of achievement.
>
> Barber et al., n.d., p. 5

The report lists evidence-based practices that are common across jurisdictions in the study, with "clear evidence in the literature that developing teachers makes the biggest contribution to student learning outcomes" (p. 6).

These meta-analyses continued at the start of the second decade of the twenty-first century. For example, the Grattan Institute (Jensen et al., 2012) in Australia took a similar approach to McKinsey & Company but focused on high-performing systems in East Asia: China Hong Kong, China Shanghai, Singapore, and South Korea. The authors found that stereotypes of East Asian education don't stand up to critical scrutiny in explaining the success of these countries; for example, Confucian culture and the influence of 'tiger mums.' While many may challenge this contention and refer also to differences in terms of the longer school day and special tutoring and coaching, the central theme is difficult to challenge, namely, the quality of teaching. These findings are consistent with those of McKinsey & Company (Barber and Mourshed, 2007). A focus of school management in these countries is on building the capacity of teachers through the preparation and selection of outstanding applicants and devoting substantial amounts of time to school-based professional development and research.

What may be the most comprehensive of meta-analyses was conducted by Hattie (2009), who synthesized more than 800 meta-analyses to specify the effects of various interventions on student achievement. He was able to rank order the effects of 138 interventions. He drew conclusions from the literature on management to identify practices with positive effects, the most successful being goal setting and team building and the last successful being 'techno-structural' interventions such as job redesign and job enrichment (Hattie, 2009, p. 85). Overall, the effects of school leadership and school management are indirect rather than direct, that is, they involve the creation of conditions under which these 138 interventions may be established and made effective.

Innovation and a Futures Perspective

The second McKinsey & Company study cited above (Mourshed et al., 2010) found that a capacity for innovation was a feature of management in high-performing systems that 'keep getting better.' There is therefore a need for leaders in schools and school systems to have a capacity for innovation. However, a case can be made that such a capacity should be nurtured in all or most settings, even those who are still on the journey from 'poor' to fair' since the context for schooling is changing in dramatic fashion. Notwithstanding the different stages in the evolution of approaches to school leadership (Murphy, 1999) or the four ways of change (Hargreaves and Shirley, 2009), the broader social and economic context was relatively stable for decades. That is not the case now, especially with advances in technology and the challenge of aligning education, society, and economy in an era of globalization. The prognosis for school management in the decade ahead is likely to include an expanded role for innovation and a 'futures perspective.'

The Merriam Webster Dictionary defines innovation as 'the introduction of something new' or 'a new idea, method, or device.' However, in education as in other settings, what might be an innovation in one school may be routine in another. A related issue is the connection between innovation, change, and reform. Innovation and reform are intersecting subsets in the broader domain of change, as illustrated in **Figure 1**. Expressed simply, not all reform is innovation; not all innovation is reform; reform and innovation are examples of change. Dealing with these relationships in different contexts is evident in school management.

In many systems of education, innovation is the responsibility of a central unit, with 'successful' innovations then scaled up for implementation across all schools. Increasingly in some settings, especially those on the journey from good to great or great to excellent (in the formulation of the second McKinsey & Company study reported above), a capacity for innovation is becoming embedded in schools themselves.

A major contribution was made by Christensen et al. (2008) with their concept of 'disruptive change' that has powerful implications for school management. Every public school principal in Victoria, Australia – about 1600 – was provided with a copy. Dyer et al. (2011) built on the concept to describe 'the innovator's DNA.' Their work was an outcome of research of over 8 years in which leaders of the most innovative companies were interviewed to determine their personal attributes. The questions were penetrating to the extent that these attributes are quite fundamental in a personal sense, hence the idea of 'the innovators DNA.' The companies were private profit-making enterprises but the authors made clear that the findings are more broadly applicable. There is no reason to believe that they are not pertinent to innovation in schools, with the authors identifying the following as the core skills: (1) associational thinking – innovative thinkers connect fields, problems, or ideas that others find unrelated; (2) questioning – innovators are consummate questioners who show a passion for inquiry; (3) observing – innovators are intense observers who gain insights into and ideas for new ways of doing things; (4) networking – innovators spend a lot of time and energy finding and testing ideas through a diverse network of individuals with different backgrounds and perspectives; and (5) experimenting – innovators are constantly trying out new experiences and piloting new ideas. The following are implications for school management: (1) every leader in every unit should have these five capacities and position descriptions and selection criteria should be changed accordingly; (2) particular attention is required to the appointment of principals and, within schools, to the appointment of staff; (3) mentors and coaches should have high levels of skill in these areas – coaches and mentors who help others reproduce the status quo may have limited value; (4) changing the culture of schools will take time; and (5) nothing in the findings and these implications suggest that a balance of leadership and management is unimportant – not every aspect of a school's operations involves innovation.

Figure 1 The relationship between change, reform, and innovation.

Leadbeater concluded that "innovation in education should take place simultaneously – at different levels and in different settings from the daily practice of teachers and learners – through organizations, systems and platforms, to the social movements and the ideologies that inspire them" (Leadbeater, 2011, p. 4).

Complementing the need for deeply embedding a capacity for innovation in school management is the importance of

gaining a 'futures perspective.' Drawing on earlier work by Mintzberg (1995); Caldwell and Loader, 2010) adopted the metaphor of 'seeing' in describing a futures-focused school. A futures-focused school 'sees ahead,' but it also 'sees behind,' honoring and extending its accomplishments in the past. It 'sees above' in the sense of understanding the policy context. It 'sees below,' demonstrating a deep understanding of the needs, interests, motivations, and aspirations of students and staff. It 'sees beside' by networking professional knowledge to take account of best practice in other schools in similar settings. It 'sees beyond' by seeking out best practice in other nations and in fields other than education. It is consistent and persistent; it 'sees it through.' The metaphor of 'sensing' is also helpful given that 'seeing' refers to what is already in place or is projected. A futures-focused school is alert to signals in its internal and external environment that may influence what may occur in the future and that may subsequently be 'seen.' These signals may be strong or weak and a high level of sensitivity is required to distinguish among them (Caldwell and Loader, 2010, p. 20; see also Caldwell et al., 2012, pp. 411, 412). The balance of leadership and management is weighted in favor of the former in the capacities required to create a futures-focused school. However, consistent with the relationships and distinctions provided by Kotter (1990), set out at the start of this article, there is a management component. Structures and processes must be established; personnel must have the required capacities; and ongoing evaluation and change are demanded.

Preparation and Ongoing Development of Those Engaged in School Management

There have been significant, if not dramatic, changes in approaches to preparing and developing those engaged in school management. These reflect the narratives provided earlier (Murphy, 1999; Hargreaves and Shirley, 2009). In summary, programs for preparation and ongoing development at the end of the twentieth century tended to be isolated from the core work of schools, namely, learning and teaching and the support of learning and teaching. As far as graduate programs in educational administration (management) were concerned, subjects like change, finance, human resource management, leadership, organizational development, planning, policy, and supervision were in vogue. Participants were expected to apply generic knowledge to areas of professional interest. Studies in curriculum and pedagogy were rarely included. There was steady change throughout the first decade of the twenty-first century, the chief feature of which has been the inclusion of studies in curriculum and pedagogy and building a capacity to analyze and utilize data on student achievement. Most school systems have established centers for leadership development and these often involve stronger partnerships between universities, school systems, and schools than existed in the past. These developments are likely to continue.

School Safety

Thomas J Mowen, University of Delaware, Newark, DE, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The safety of schools in the United States has always been a concern to policy makers, teachers, parents, and students. However, over the past three decades, there has been an increase in the concern over school safety given the highly publicized shootings of the 1990s and 2000s. As a result, schools are employing more security measures to ensure the safety of schools, and policy makers and school administrators are implementing more and more policies aimed at maintaining safe schools.

Introduction

Schools in the United States are often considered safety zones for youth and young adults. While neighborhoods, certain areas of town, or even the home environment may be potential places of violence for children, schools have traditionally been a safe haven for all youth in the minds of most Americans. The reality is that all schools must deal with issues of violence and threats against the school or members of the school. Because of this, all schools must also deal with how to maintain a safe school environment. Certainly the degree to which a school must consider threats varies due to myriad factors. For example, the way in which a suburban school secures its' hallways is likely very different than the means employed by an urban or rural school. Overall, however, the safety of schools in the United States has occupied an important position in educational policy since the introduction of the formal educational system in the United States.

School safety exists, of course, in response to perceived threats to the well-being of the educational institution, as well as the well-being of the individual members of the institution including students, staff, administration, family members, and anyone within the school or involved in school business. Because of this, school safety can take on many forms and many meanings; it changes over time and between spaces. For example, the instruments of school safety used in modern schools are very different than the instruments used in schools of the 1930s and 1940s. Similarly, school policies and practices aimed at protecting the school have also changed over time. This is due, in large part, because the concern of school safety; that is, what the safety is guarding against, has shifted drastically over the past half century.

Defining School Safety Over Time

School safety is comprised of two primary areas of concern: (1) threats to the school from external forces such as individuals who may seek to burglarize the school, for example, or threaten the safety of students and staff members; and (2) threats to the school from internal sources such as student misbehavior, teacher, and staff misconduct, or other crimes committed from someone within the school. As subsequent sections will highlight, the former area of concern has received significantly more attention than the latter. Given this duality of concern, however, it is important to consider how defining and understanding school safety is bound within time.

The goals and instruments of school safety – like most anything – have evolved over time. Documents reveal that in the 1930s and 1940s, the concern of school safety was aimed at discouraging children from speaking out of turn, or encouraging students to dispose of their trash in a proper manner. There is little evidence that school officials were considered with any school safety policy aimed at deterring threats outside of the school; the focus was aimed exclusively at reducing minor misbehavior by students (Stouffer, 1952).

Moving into the 1960s and 1970s, highly publicized events such as the Civil Rights Movement, and other national-level events such as the Vietnam War highlighted the importance of safety in the nation. As a result, schools began to target more aggressive forms of problem behavior such as student–teacher disobedience, and physical confrontations between students. In addition, school policies aimed at reducing drug use and gang activity began to emerge within the school security discourse.

Transitioning into the 1980s and early 1990s, as the United States Department of Justice intensified the war on crime, schools and policy makers became concerned with guns, gang violence, and drug violence. Because of this rise in concern, zero tolerances policies (outlined in subsequent sections) quickly gained ascendancy into the school safety conversation, and have continued to dominate educational policy.

The 2000s and 2010s have seen a number of highly sensationalized school shootings including Columbine, Virginia Tech, and more recently, the shootings at an elementary school in Newtown, Connecticut. Such events changed the way in which school safety is regarded. These recent events have resulted in a drastic rise in concern over safety in the hallways of American schools (see Casella, 2006). Because of this, researchers, policy makers, and parents have turned their attention to understanding what makes schools safe, and how can threats to the school be neutralized or avoided.

The Rise of Zero Tolerance

Prompted by the increased awareness and attention given to the threat of gangs and gun violence in the hallways of American schools, the late 1980s saw the ascendency of zero tolerance policies within American schools. Though initially a term

used by the Drug Enforcement Agency regarding illegal shipping containers in the mid-1980s, zero tolerance school policies quickly gained rapid ascension beginning in the late 1980s. By 1989, nearly half of all state school systems had adopted a zero tolerance perceptive on drugs and gangs (Phaneuf, 2009), and by 1990, nearly 80% of all public school systems in the United States employed some level of zero tolerance.

As previously highlighted, zero tolerance is the primary method of employing discipline and punishment on students within the school. Zero tolerance refers to giving no leniency for particular crimes; that is, punishments become required at a minimum for particular offenses. The goal of zero tolerance is twofold. First, it sends a clear message to students that particular offenses will not be tolerated. Second, it is aimed to ensure that all punishments given by an administrator are uniform based on the zero tolerance policy. Thus, it encompasses both a deterrent effect, while providing uniformity in discipline, creating a sense of equality among diverse student bodies. Because of this, forms of zero tolerance exist in nearly all schools across the United States.

In 1994, with the passage of the Gun-Free Schools Act, public schools in the United States became legally required to expel students from school for no less than 1 year if they were found with a gun on school grounds. The law, as it was originally drafted by the United States Congress, was narrowly focused on dangerous weapon possessions – such as guns and explosives – within the school proper (Sughrue, 2003). However, by 1995, most schools had voluntarily expanded the scope of this bill to include other weapons such as daggers, knives, brass knuckles, and lighters. As other scholars highlight, many schools also voluntarily expanded zero tolerance to include destruction of property, nonviolent repeated defiance of school authority (Insley, 2001), possession of over-the-counter pain relievers, toy guns, and classroom disruption (Schwartz and Len, 2001).

As noted above, there are some levels of zero tolerance that are mandated by law. For example, it is likely that if a student were found with a gun in any school, they would face a minimum sentence of a 1-year expulsion and also face legal prosecution. However, not all schools have zero tolerance for more minor behavior such as repeated defiance of school authority or destruction of school property. Thus, while most schools in the United States employ some level of zero tolerance, but there are important variations. Public schools are much more likely to employ a greater number of zero tolerance policies than private schools. High school and middle schools are more likely to use a greater degree of zero tolerance than elementary schools. Finally, urban schools are more likely to use zero tolerance policies than rural or suburban schools.

Columbine Aftermath

On 20 April 1999, two students at Columbine High School in Colorado committed suicide, but not before killing 12 students, one teacher, and injuring 21 other individuals during a premeditated takeover of the high school. Perhaps more so than any other single event in the history of schooling in the United States, this event reverberated throughout the nation. In turn, this prompted lawmakers, administrators, and policy makers to review the safety of schools in the United States. The outcome of this was the Safe School Initiative (SSI). The goal of the SSI was to explore past violence in schools, and to implement a series of best practices for schools to engage in order to reduce the risk of school shootings in the future.

The SSI, a collaboration between the National Threat Assessment Center, the US Department of Education, and the US Secret Service is one of the most ambitious and lengthy studies on school safety in the Unites States to date. The study examined 37 lethal shootings involving 41 attackers that occurred in schools between 1974 and 2000. The research teams examined school records, school security instruments present, demographic information, and other pertinent details that shed light on these acts of school violence. The final report highlighted 10 major findings, which are presented below along with additional comments concerning the outcome of each point.

1. Incidents of targeted violence at school rarely are sudden impulsive acts.

It is important to note that although a violent act occurring within the school is not necessarily impulsive, the time between when the attacker decides to carry out violence against the school and the execution of the plan may not be long enough for proper intervention. At the same time, however, the results of the SSI reveal that most of the incidences involved detailed planning of the act before execution. This finding suggests that if 'at risk' students can be identified, it may be possible to provide resources to the student and the student's family that could potentially result in a different outcome.

2. Prior to most incidents, other people knew about the attacker's idea and/or plan to attack. In most cases, those who knew were other kids–friends, schoolmates, siblings, and others. However, this information rarely made its way to an adult.

This key is especially important as it suggests that other students or friends may be in a position to intervene, or pass important information onto an adult. The SSI suggests that schools should ensure they have a fair way of responding to concerns of students. Thus, school safety policy should encourage communication between students and adults, and provide an avenue for the students to reach out without placing themselves at risk.

3. Most attackers did not threaten their targets directly prior to advancing the attack.

According to the SSI, this point underscores the importance of acting on any information that may indicate a problematic situation; not simply waiting for a threat to materialize. Moreover, the report concludes that school administrators should respond to any threat made by students, regardless of how small.

4. There is no accurate or useful 'profile' of students who engaged in targeted school violence.

Such findings indicate that profiling a student based on sociodemographic factors, lifestyle choices, such as clothing or musical tastes, are not useful methods in predicting whether or not a student who may become violent. This is especially

relevant as one of the outcomes of Columbine was many parents and policy makers pointed to Marylyn Manson and the 'goth' lifestyle as inspiring the violence that occurred. Likewise, the shooting in Newton, CT, has inspired great debate over the prevalence and influence of violent video games. Yet, research has yet to establish any 'profile' of students who may engage in school shootings, and the SSI underscores that this would be a fruitless endeavor.

5. Most attackers engaged in some behavior prior to the incident that caused others concern or indicated a need for help.

Overall, this recommendation suggests that a truly safe school cannot simply surround itself with defense objects such as metal detectors and police officers (discussed in subsequent sections) to prevent school tragedies and increase school safety. While security instruments play an important role in preventing school shootings, school officials must be trained to recognize calls for help from at risk students. Moreover, this finding suggests that most troubled youth do show some visible signs of distress that can be recognized. One of the tangible outcomes of this report was an increase in school counselors and school psychologists available to students in many schools.

6. Most attackers had difficulty coping with significant loses or personal failures. Moreover, many had considered or attempted suicide.

It is also important to highlight – and the SSI does – that most students who experience a loss in life will not become attackers within their school. However, the majority of cases investigated by the DoE experienced personal failures or loses. This finding suggests that school staff and administration should pay attention to students experiencing hardship, not simply because they 'may' become a danger to the school, but because the school is viewed as a safe haven (see also Dwyer et al., 1998). A closer integration between the private life of the student, and the students' school life may be an effective way to reduce school shootings and increase the safety of the school.

7. Many attackers felt bullied, persecuted, or injured by others prior to the attack.

As with the above point, not all students who are bullied are problematic, but the vast majority of cases investigated had students who experienced bullying and were often classified as social outcasts by other students, teachers, and staff. Moreover, bullying has recently received a significant attention at the national level. Recently, increased legislative attention to bullying has resulted in the government launching specific programs designed to reduce bullying within the school including the launch of a government website aimed specifically at reducing bullying within schools (United States Department of Health and Human Services, 2013).

8. Most attackers had access to and had used weapons prior to the attack.

The issue of gun control falls outside of the scope of the current article, but the implications of this finding suggests that if it were more difficult for students to gain access to guns it *may* be possible that difficulty could serve as a deterrent. While students could turn to other forms of weapons, such as knives, it is likely that within access to a gun, the number of lives lost due to an attack within the school would be much less. Such thoughts are gaining popularity as shown by the passage of the strictest gun control law in the nation in Connecticut, the home state of the school shooting in Newton.

9. In many cases, other students were involved in some capacity.

Much like point 2, this finding suggests that friends and other students may be able to provide feedback to troubled individuals in deterring them from engaging in an attack. At the same time, however, it also suggests that students may not have believed that the individual would carry out an attack. Because of this, school officials should encourage students to come forward with any concern, no matter how small.

10. Despite prompt law enforcement responses, most shooting incidents were stopped by means other than law enforcement intervention.

Again, this highlights the need for schools to focus not just on defensive technologies, but also on training of school staff to recognize potential situations, and to defuse situations and seek treatment for the troubled individuals. It also suggests that an increase in security guards may not be enough to prevent school shootings.

Overall, the conclusions of the SSI suggest that many of the attacks may have been preventable. The Department of Education concludes that schools should actively, and continually, engage in threat assessment and develop strategies to prevent potential attacks on the school from occurring. In large part, this document has resulted in schools adopting greater numbers and types of school security measures and policy.

Instruments of School Safety

As highlighted by the SSI, one of the major takeaways was the implementation and use of school security measures. As of 2010, the most currently available data, nearly 98% of all schools in the Unites States control access to their grounds through check in areas. Approximately 80% of schools maintain a closed campus during the entire school day, requiring students to stay within the school and school groups; 21% of all schools utilize metal detectors at the entrance of the school; 69% utilize random drug sweeps on the student bottom to search for contraband; nearly 75% utilize security cameras or closed-circuit televisions; and approximately 55% of all schools utilize a police or school resource officers (U.S. Department of Education, 2012). The overall goal of these measures is to increase the safety for students, teachers, parents, and other stakeholders within the school.

It's important to highlight that the types of school safety instruments used vary by region, school type, and school size. Larger schools are more likely than smaller schools to utilize any instrument of school security measure outlined above. This is due, in part, to the budget of the school, as well as the location. Similarly, public schools – which tend to be larger than private schools – tend to employ more instruments of school security. Urban schools, as opposed to rural and

suburban schools, are the most likely to utilize instruments of school security. Finally, schools in the Southern United States are more likely to use instruments of school security compared to schools in the Midwest or Northeast regions of the United States.

In addition to the use of school security instruments, school administrators and policy makers also rely on the use of detentions, suspensions, and in the most severe cases, expulsions as a means to regulate the behavior of students. As of 2006, approximately 6.9% of all students in the United States had received a suspension at some point over the course of their schooling. While data are not easily accessible, this rate has increased from 3.7% of all students in 1974. At the same time, expulsion rates have remained relatively stable since 2000 with approximately 0.2% of all students having been subject to expulsion has a form of punishment. Please see **Table 1**.

School Safety, Drugs, and Gangs

The major impact of the Columbine incident is only part of the story in explaining how policy and procedures have been shaped in order to keep schools a safe place. While school shootings have become a more pressing concern in recent years, one major concern of school safety efforts is focused on reducing the availability of drugs and illegal substances within the school. This concern gained ascendency in the early 1980s as the United States moved into the period of War on Drugs, but it is important to note that there have been many fluctuations in the amount of drugs within American schools, and there have been many changes in policy to address drug use and school safety.

A University of Michigan-based report entitled Monitoring the Future (MTF) has studied drug use within schools since 1975. That year, the study concluded that approximately 55% of all students in the United States had used an illicit substance prior to graduating high school. While this does not mean that illicit substances were used within the school, but studies such as MTF find that most youth who engage in illegal substance abuse generally procure the means to get the drug through the school. Moving forward, by 1981, this number increased to 66%, but soon after began to decline finally setting on a low of 41% in 1991 before rising to 55% in 1999. In recent years, this number has dropped to approximately 44% by 2006 where it has remained relatively stable since (MTF, 2012). MTF reports that marijuana is the most used drug by students, and most students who consume marijuana receive the drug through contacts within the school.

Such findings highlight the important role school security measures and school safety policy play in the reducing of the availability of drugs to students in school. At the same time, however, it is not possible for security measures/policy to effectively clear drugs from schools. It is interesting to note that as schools began to use more security measures (see the above section), the number of students reporting drugs dropped. Although that number has bounced between 40 and 55% over the last two decades, it is interesting to note that the number of students reporting drugs has never reached 'pre'modern security measure and zero tolerance numbers.

The second major concern of school safety – also growing out the 1980s – is that of gangs and violence within schools. While research is mixed on the extent to which gangs operate within the school, gang activity is a major concern. For example, research has found that most gang members are not interested in attending school, and gang activity is often regulated by zero tolerance. Because of this, students who are members of a gang are often faced with expulsion. Individuals that support this view often show that gangs, overall, do not operate within schools to a significant degree compared to their presence outside of the school.

At the same time, no one denies that gang activity, when it is present, is problematic within schools, and school security measures and policy must be implemented to dissuade gangs from operating within schools. As a recent report by the Bureau of Justice Assistance highlights, youth – including youth who are involved with gangs – have a legal right to an education from public schools in the United States and because of this, gang activity will continue to persist (U.S. Department of Justice, 1999). Therefore, schools continue to take action and implement school security policies to deter gang activity.

Side Effects of School Safety Measures

While it is important to assess the relative success of school safety on reducing the presence of drugs, gangs, and violence in schools, there have also been a number of studies that have assessed other outcomes of school safety, namely, the effect of school safety on students. Recent works have found a strong racial imbalance in the application of punishment (Skiba et al., 2000) with Black and Hispanic students significantly more likely to be expelled or suspended compared to White students for similar misbehaviors. In addition, Black males are

more likely to be punished for minor misbehavior than males of any other race. Not surprisingly, projects have also found that Black students are more likely than White students to perceive that discipline is applied unfairly (Kupchik and Ellis, 2008).

Others have become considered with the authoritative nature of school security and policies. For example, many researchers and scholars argue that the modern school is one that is focused more on the safety and security of the schools, and less with the true goal of education. On the other hand, some research has found that school disciplinary policy and school security measures are becoming so increasingly common that students have become desensitized to having to walk through metal detectors or encounter police officers in the hallway of their school (Bracy, 2010). In this sense, school safety police and practice has become normalized for many students in the US schools.

Clearly, these bodies of literature do not suggest that there should not be school security measures and policy within the school. Instead, these scholars show that there may be important side effects of zero tolerance and other policies that do not just affect the safety of students in the school. The question, for many, revolves around understanding where the balance between safety and autonomy lies, something that will, no doubt, be further explored in the future.

The Future of School Safety

In light of recent tragic acts of violence that have taken place in schools around the country, the safety of the hallways in the US schools remains a pressing and important issue. While no one can predict what events in the future will change how we protect the nation's schools, we do know that parents, teachers, administrators, and policy makers will continue to play a pivotal role in protecting America's youth within the institution of education. While no single national reformatory proposal has been, or probably will be, universally embraced, most groups agree maintaining appropriate safety structures within each school to safeguard the nation's youth against violence will remain a top priority for everyone involved.

School to School Collaboration

Abstract

Contemporary education is a complex endeavor, and educators have come to value collaboration as a vehicle for accomplishing its purposes. Collaboration is the style educators use when they partner to achieve shared goals. It is based on voluntariness, parity, shared responsibility for key decisions, shared accountability for outcomes, and shared resources. Collaboration matures with ongoing implementation. Contemporary applications of collaboration include those that are intraschool (teams, professional learning communities, consultation, team teaching, co-teaching) and extra-school (school-to-school collaboration and other partnerships, including those with parents). Challenges to collaboration include clear evidence of its efficacy derived from research, the lack of supportiveness of some school cultures, professionals' preparation for collaborative roles, and availability of time for collaboration as well as other practical barriers. In spite of such challenges, collaboration's importance for education is likely to continue to grow.

Introduction

Although teaching was once considered a profession characterized by isolation, such is no longer the case. This change has been driven by many forces, including the exponentially expanding amount of information in today's world, the rapidly increasing role of technology in schooling, pressures coming from business and industry as they evolve in this second decade of the twenty-first century, the worldwide movement to include individuals with disabilities, and ongoing school reform efforts. The result is that educators have recognized that their complementary but disparate abilities and talents can be shared in order to design effective and innovative instruction, create supportive but rigorous learning environments, solve the many problems they face each day, and generally improve outcomes for all students (Friend and Cook, 1990; McCoach et al., 2010).

In some ways, though, the use of the term *collaboration* has outstripped technical understandings of it and the knowledge based on its practice. That is, collaboration at times seems to be a panacea: It is referenced frequently in the education literature but often in vague or confusing ways. It has been employed to describe any interaction among adults in schools as well as those between school professionals and parents, agency personnel, and community members (e.g., Kampwirth and Powers, 2012). Collaboration has also been assigned to the communication that occurs between adults and children or activities undertaken by groups of children (e.g., Gailbreath and Winterbottom, 2011). Clearly, this range of uses suggests incomplete understanding. Unfortunately, it also sometimes results in professionals forming a negative perception of this essential dimension of contemporary education.

The purpose of this article is to explicate the concept of collaboration as it occurs in school-related settings, also placing it in the context of a larger society, and to describe several of its most common applications in today's schools. In addition, challenges related to professional school collaboration are considered, and conclusions are offered concerning enhancing its current and future implementation.

Conceptual Underpinnings of Collaboration in Education

In everyday parlance, collaboration connotes camaraderie or partnership. However, for professionals it is important to understand its technical meaning and characteristics as well as its prominence in a larger societal context.

A Technical Definition of Collaboration

According to Friend and Cook (2013), collaboration is "an interpersonal style for direct interaction between at least two coequal parties voluntarily engaged in shared decision-making as they work toward a common goal" (p. 6). Two especially central elements of this definition are these: first, as a style, collaboration represents how individual interact rather than what they are interacting about. This is a critical concept. It suggests that any interaction between educators or educators and parents may be collaborative, if that interaction meets the other criteria of the definition. It also infers that other styles exist, and they do. For example, some interactions are directive, in which one individual directly or indirectly guides the other (e.g., 'you should …'). Second, the definition implies that collaboration cannot stand alone; it always is attached to a substantive topic or process. If a professional reports that she/he is collaborating, it only suggests a style; the subject on which the style is focused and the process being used (e.g., problem solving) remain unknown.

Foundational Characteristics

Reviewing the definition of collaboration is a mere first step in understanding its role in schools. Exploring the foundational characteristics that complete the definition of collaboration illustrates its complexity.

Collaboration Is Voluntary

School administrators and other school leaders often have the appropriate responsibility of assigning teachers and others to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92129-9

work together; they determine which individuals will work in proximity, often with the assumption that collaboration will occur. However, it is the participants who choose whether to use the style of collaboration. For example, a school team is created to problem solve about students who struggle academically. This proximity was mandated. However, on one such team members actively contribute, respect all opinions, and keep in mind the goal of improving student achievement. On another team, one person tends to avoid participation, annoyed at being assigned to work on the team. Another argues repeatedly for only his/her ideas, often without considering the value of others' recommendations. The former is collaborative; the latter, obviously, is not. And yet in both cases, membership was assigned.

Collaboration Requires Parity

The contribution of each individual who is part of collaboration must be equally valued. Further, collaborators must share equal power in critical decision making. This does not mean that participants necessarily have parity in interactions outside the collaborative endeavor. For example, a principal and a teacher must have parity if they are collaborating about adopting a new instructional program, even if typically this is not the nature of their professional relationship. It should be noted, too, that parity is often much more complex than implied here, at least in part because it can be profoundly influenced by perception and culture.

Collaboration Includes Mutual Goals

Collaboration is not possible unless participants identify goals that they share. They may have other goals that potentially are in conflict or are unrelated, but at least one mutual goal must be critical enough to be worthy of setting differences aside. For example, professionals may come together to problem solve about a student's behavior. However, if some members are seeking a means of removing the student from class while others are working to keep the student there, collaboration is unlikely, even if all participants agree they want to 'help' the student. A conversation about goals in this case would be essential.

Collaboration Requires Shared Responsibility for Key Decision Making

When school professionals collaborate they actively contribute to making key decisions, whether they concern a new data collection strategy, a new instructional program, a common assessment strategy to be used, or an intervention to assist a student's learning. In today's busy work settings, a common piece of advice is that collaborators should share key decisions related to accomplishing their goal so that they are comfortable in their knowledge of what is planned, but they should divide the labor involved so that it can be accomplished efficiently and effectively – but not necessarily shared.

Collaboration Requires Shared Resources

Limited resources often are one of the most profound reasons school professionals seek to collaborate. The pooling of resources may be the only way to reach a goal. These can be tangible resources, such as materials; skills, such as a teaching methodology or knowledge of particular academic content; a specialized understanding, such as familiarity with and experience in working with students with autism; or availability to complete a particular task that is key to the success of the group.

Collaboration Requires Shared Accountability

When collaboration leads to success, participants are eager to share in the accomplishment, but if the effort is not successful or even led to additional challenges, participants may distance themselves from the outcome. Taking ownership of the entire process with the understanding that there sometimes will be setbacks when working toward a goal is required for members of a collaborative group. This sustains the group through hardships and unexpected challenges, ensures the best possible environment to attain the shared goal, and fosters celebration of goal attainment.

Emergent Characteristics

Collaboration also has emergent characteristics. These characteristics must be present in some minimal way at the outset of collaboration, but they then develop over time as the collaborative relationship strengthens because of its success. Emergent characteristics include trust among participants, accompanied by respect for what each contributes to the endeavor. Gradually, a deep sense of community is cultivated. The developmental nature of collaboration is relevant because participants may need to persist through early, less-than-satisfactory interactions in order to eventually reach a strong and productive relationship.

Collaboration in a Broader Context

The concept of collaboration is by no means limited to the educational arena; it is integral to many aspects of business and industry as well as the medical and health fields. In fact, successful businesses have noted the impact on efficiency and the importance of having professionals who can collaborate since the 1950s (Blanton and Kenett, 2007; Ishikawa, 1990; Juran, 1962). A similar history can be found in the medical community where the interprofessional nature of health care is seen as a means of collecting more sensitive and broader patient assessments with higher reliability of decisions (Zwarenstein and Reeves, 2006).

The use of collaboration in schools as a reflection of larger societal trends can perhaps be best illustrated by current trends and priorities in the business world. It is widely acknowledged that today's business climate makes collaboration a necessity rather than a luxury. Globalization of the marketplace, the amount and complexity of data that must be managed, and the speed at which change occurs all indicate to business leaders that close and carefully engineered partnerships, formed both internally and externally, are foundational to success (Beier, 2014). These leaders are urged to seek job candidates with strong potential to work collaboratively, to encourage collaborative practices by distributing leadership among employees, and to create teams and other internal structures that foster the enriched outcomes created through collaboration (Jensen, 2013; Miller and Katz, 2014). Additionally, contemporary collaboration in business environments does not necessarily

rely on face-to-face interactions. Strong emphasis is placed on electronic collaboration and its potential to facilitate interactions among participants from around the world in effective and efficient ways (Boeri, 2012). What is clear is that collaboration in many forms has become a central element of business success and is likely to continue to grow in prominence and sophistication.

Applications of Collaboration in Educational Endeavors

Although school professionals may not yet be implementing collaborative activities in the ways being pioneered in business settings, the number of applications and their importance in achieving the goals of education have expanded over the past two decades. The following are brief descriptions of the most typical types of school collaboration.

Intraschool Examples of Collaboration

Most school collaboration is focused on the working relationships among professionals and between professionals and parents. All of these partnerships are intended to pool the knowledge and expertise of the participants in a way that leads to improvement in student academic achievement as well as in student social and behavioral well-being.

Teams

Teams are an increasingly common collaboration structure in today's schools. A *team* is an interdependent group of individuals who share their knowledge and skills in order to accomplish a mutual and clearly articulated goal, usually related to improving student outcomes. The assumptions for creating teams are that the task at hand is too complex to be reached by a single individual and that multiple perspectives will lead to more positive results.

Effective teams share several characteristics that have been well researched, both in education and in other domains, including business and health occupations (e.g., Bang et al., 2010). First, teams have clear goals. Without such goals, there is no purpose for this group of individuals to interact. Second, team members are aware of and committed to their membership in the group and the accompanying responsibilities for meaningful participation. Although this characteristic seems almost too fundamental to mention, it sometimes is an issue: Educators occasionally do not recognize the need for them to actively contribute, to work on team goals outside meetings, and to put the work of the team above individual agendas.

Third, teams formally or informally adopt shared norms. That is, they have a set of expectations related to their actions when they interact during meetings, procedures they follow, expectations for work completion outside of meetings, and so on. This leads to the fourth characteristic of teams: Team members have a strong sense of interdependence, the understanding that it is the shared effort that will lead to a positive result. Finally, effective teams are comprised of members who have different types of expertise. If participants are similar, they are less likely to generate creative options; if they have a wide range of knowledge and skills, more and higher quality solutions are likely to result.

School teams may be formed for a variety of reasons. In some locales, they exist to implement schoolwide systems intended to address students who are struggling academically or behaviorally, such as response to intervention, positive behavior supports, or multitiered systems of support. They also are integral to the special education/special educational needs process in which students who may have disabilities are assessed, their eligibility for services determined, and the amount and nature of such services decided. Finally, school teams may be formed for narrower but critical work such as redesigning systems for including students with special needs, selecting and implementing new curricula, incorporating technology into existing programs, or addressing a problem or issue confronting the school.

One currently popular example of school teaming is a professional learning community (PLC). A PLC may consist of teachers on the same grade level, a curriculum coach, possibly an administrator and also other specialized professionals who meet on a scheduled basis. This may be all high school English teachers, a curriculum coach, and a special education teacher coming together to learn about the new English curriculum. On a specified day, twice per month, teachers may meet to share information from various sources regarding the curriculum. They may monitor student outcomes through data analysis of a common unit assessment all the teachers have administered. They then may develop strategies for struggling learners. Each member of the group may take a lead role at various times, depending on the topic at hand. For example, one member may take the lead on discussion of a book about literacy grouping and facilitate the development of methods for further instruction. Another member may take the lead on facilitating analysis of student data. PLCs are intended to function for at least an entire school year and require a collective commitment. Specifically, there must be a collective commitment to the collaborative effort, to the success of each student, and to high levels of learning for PLCs to be effective (Dufour et al., 2006; Dufour, 2004).

School teams may face challenges in accomplishing their goals. For example, time to meet may be limited, especially when various professionals may have schedules that may be difficult to coordinate. In addition, each participant must fully and actively commit to the team's work; if some individuals, perhaps assigned to the team but unwillingly so, isolate themselves, the team's goal is unlikely to be met. Finally, the differences among team members that provide team strength also can make interdependence difficult: When members represent different areas of specialization, come from different cultures, or possibly have different primary interests, teaming requires extraordinary effort and discipline.

Consultation

Consultation has long been recognized as a valuable tool for supporting students with a wide variety of special needs and their teachers. Drawing from earlier applications in the medical professions, consultation began in schools in the middle of the twentieth century primarily as a role for school psychologists and other specialists. Its purpose was to educate teachers about their students who needed support because there simply were

not enough school psychologists (nor would there ever be) to directly intervene with each needy student. In more recent years, consultation has expanded to include teacher–teacher interactions as well as coaching and mentoring. Most importantly, it has shifted from directive models to those based on collaboration. In general, consultation is a process in which one professional with a particular type of expertise provides support or guidance to another professional in order to address a concern or problem related to a third party, usually a student. The result is that the third party is supported but also that the teacher acquires skills for addressing similar situations in the future.

Consultation typically follows a series of steps that can be characterized as specialized problem solving (Newell, 2010). It is premised on professionals' willing participation, and the understanding that, while the person functioning as the expert may learn from the consultee, the goal is directional, that is, the process is undertaken to assist the latter individual. Because of this arrangement, consultants and consultees have different responsibilities and accountability. Consultants are responsible for diligently striving to understand the issue at hand, for offering ideas and strategies that are ethical and feasible, and for supporting the consultee's implementation of those suggestions, interpreting results, and continuing the process until success is achieved. The consultee is responsible for accurately describing the dilemma to be addressed, carefully implementing the consultant's suggestions, gathering needed data, and being willing to persist if additional options need to be explored.

Consultation often is employed when teachers find that they are not being successful in meeting a student's needs. This could pertain to a student who has unusual behaviors, a student who is exceptionally gifted or talented, a student with a particular disorder such as autism, or a class group experiencing extraordinary problems in social interactions. In another application, early career educators may work with a mentor consultant to refine their overall instructional or classroom management skills and to have a successful induction into the profession (Ingersoll and Strong, 2011). Coaching also sometimes is a consultation strategy (Gallucci et al., 2010): For example, if a new reading program is introduced at the elementary school level, a coach may demonstrate for teachers how to complete required instructional activities, occasionally spending time in the classroom but also meeting at other times to discuss progress in implementation.

When specialists consult with teachers and collaboration is stressed, its effectiveness is well established. Far less is known about teacher–teacher consultation. The latter can be complicated by several factors, including the value placed on and the perceived appropriateness of shared peer expertise, the availability of time, and the skills of both the teacher consultant and the teacher consultee. Regardless of who serves in the consulting role, effectiveness is determined by perceived relevance and feasibility of the strategies offered, their immediate impact on the identified concern, and the quality of the relationship between the participants.

Team Teaching

Begun as a high school instructional model in Great Britain and intended to draw on teachers' particular areas of content expertise, team teaching originally consisted of one teacher delivering a lecture to a large group of students, and other teachers providing follow-up, discussing the content, responding to student questions, and monitoring student understanding (Geen, 1985; Warwick, 1971). In the US, this approach was adopted as the Trump model. Over time, it evolved into a variety of contemporary applications. Today, team teaching refers to an instructional arrangement in which two (or more) teachers, each with an assigned full-class group of students, share instructional responsibilities for all or part of the school day.

The key characteristics of this model include the following: First, the teachers involved may have similar or different content expertise. In some instances two elementary teachers use team teaching, blending their classes in order to better differentiate instruction, and so their expertise is similar. In high school, a history teacher and a literature teacher may blend their classes with the goal of teaching history through literature, each contributing their unique expertise. In addition, this application of collaboration implies that joint teaching occurs, but that is not always the case. In schools using a middle school model, for example, four teachers may share responsibility for a group of 100 or more students and plan coordinated instructional activities, but they may not teach together. Further, in most examples of team teaching, the teacher-to-student ratio is constant. In a few applications, though, two teachers may be partnered to teach a single class group, sometimes to improve overall classroom management and occasionally because there happens to be a teacher available for this purpose.

The examples already provided begin to illustrate how team teaching is occurring in today's schools. Other uses of this approach may include multigrade teaching opportunities at the elementary school level or even the option for language immersion (for example, a Spanish teacher and an elementary teacher working with a large group of students for all or part of the school day). In middle and high schools, many examples can be found embedded in the trend to integrate disciplines. For example, science and math teaching may be blended with students applying their mathematical learning in a biology or physics course, led by two teachers. In another example, two teachers lead a student group in a blended anatomy and physical education class.

Several issues can arise with team teaching. First, the professionals participating must have a collaborative relationship that fosters the blending of their discipline-specific expertise. Second, each must be committed to this type of integrated instruction and partner to contribute to its content so that students have adequate coverage of both subject areas. In addition, a physical space conducive to team teaching must be available, that is, a classroom or teaching area that can accommodate two or possibly more class groups of students.

Co-Teaching

The origins of co-teaching lie in the early school inclusion efforts of the 1980s, but its recent increased utilization is the result of the worldwide trend toward inclusive practices as well as school reform initiatives designed to ensure access and achievement for all learners. Co-teaching is the instructional model in which two or more professionals, most often

a general education teacher and a special education teacher, jointly deliver instruction to a diverse group of students in a shared classroom space, an arrangement that may occur for the entire school day or for a specified amount of time or class period.

A key characteristic of co-teaching is the contribution that each professional makes. For example, a special education teacher may work with a general education teacher in math class. The general education teacher's appropriate primary focus is on content and pacing while the special educator incorporates specialized techniques to facilitate the learning of students with special needs. Because successful co-teaching relies on trust between the teachers and strong willingness to share authority in the classroom, collaboration is essential.

Specific co-teaching approaches have been identified that maximize this instructional option (Friend, 2014). These are summarized in **Table 1**, although creative practitioners have added many variations to the basic structures.

Effective co-teachers employ the approaches based on student need and the nature of the planned instruction, fluidly moving among them across lessons or even within a single lesson. For example, in the math example already introduced and using station teaching, one teacher might work with students on vocabulary, one might introduce new concepts, and the students might independently work on a problem solving activity based on previous learning. The math teacher's responsibility is to be sure the new concepts are clearly presented; the special educator's responsibility is to embed in the instruction learning strategies to help students remember the vocabulary as well as the new concepts.

Co-teaching is a sophisticated collaboration application influenced strongly by professionals' working relationships. Patterns or expectations relate to diversity can directly affect co-teachers' shared instruction. For example, a male teacher from a culture in which women should defer to men's judgment may find co-teaching difficult with a female co-teacher. Ultimately, one of the most important elements of co-teaching is flexibility.

Table 1 Co-teaching approaches

Co-teaching approach	*Description*
One teaching, one observing	One teacher is solely responsible for the delivery of instruction while the other teacher gathers data on student performance.
Station teaching	Students are divided into three groups and rotated through three instructional activities, two of which are facilitated by teachers and one completed independently.
Parallel teaching	Each teacher is actively teaching during the lesson but may use slightly different strategies to teach the same concepts.
Alternative teaching	One teacher is responsible for large group instruction while the other teacher focuses on small-group work in which instructional goals may be different.
Teaming	Teachers work in complementary ways during a lesson, working toward the same goals. Instructional leadership is shared and integrated.
One teaching, one assisting	One teacher leads instruction of the whole class while the other teacher assists students individually.

Extra-School Examples of Collaboration

School applications of collaboration are not limited to those that occur among the professionals at a single site. School professionals have recognized the benefits of collaboration outside their educational setting to enhance instructional techniques, share resources, and improve learning opportunities for students. Such collaboration includes that which occurs between schools and agencies that which is school-to-school.

School–Agency Collaboration

Educators in many schools have reason to collaborate with professionals in other organizations or agencies. For example, specialists working with young children with developmental delays often collaborate across multiple organizations (and, of course, with parents) to provide services to these at-risk students. Special programs for at-risk youngsters, social services, and other agencies serving families all may participate in efforts to design and deliver early education for the children. School professionals also may work with community agency personnel to provide social, mental health, or medical assistance for children and families and to transition children through different school experiences. Each agency may have a focused goal for the child, but those goals are part of the larger collaborative goal of supporting parents and children.

School-To-School Collaboration

Many types of school-to-school collaboration have been reported in the professional literature. These partnerships may occur between schools at the same level of instruction. For example, fourth grade teachers in one primary school partner with teachers in another primary school in the same school district to make common assessments for shared units of curriculum. Another form of school-to-school collaboration includes schools of different levels of instruction. For example, secondary school teachers plan with teachers from a primary school to create a tutoring program that will assist the younger students and create option for service for the older students.

One compelling example of school-to-school collaboration is the Afri Twin project. In this ambitious initiative 75 South African primary and secondary schools were paired with 75 comparable schools in Britain and then 'twinned' with a third school in a rural area (Klerk and Nienaber, 2011). Each group of three schools shared one common goal and focused on forging of friendships and improving communication skills. The schools shared resources by building international links, creating a two-way knowledge transfer, and learning alternative skills and values. In addition, the project addressed parity and diversity issues by stressing pride, self-esteem, and personal growth for all participants, and it fostered racial tolerance.

The Complexity of Collaboration in Education

Given the importance of collaboration for contemporary schooling and the many collaborative applications that are

enabling educators to optimize their students' learning, it might seem that the road forward would be obvious, that is, continue to foster collaborative practices and ensure they are sustainable. However, a number of complexities ensure that the future of school collaboration is neither readily apparent nor a particularly straight path.

The Evidence Base for School Collaboration

One potential barrier to expanding collaborative applications in schools is the paucity of rigorous studies related to them. Some evidence does exist, but it often comes from evaluation studies or anecdotal reports rather than from traditional experimental research (e.g., Solis et al., 2012). In fact, collaboration occasionally has been criticized as tangential to effective education practices or a distraction from them.

Part of the reason for the dearth of research is the very nature of collaboration. That is, as noted at the beginning of this article, it never exists by itself but is always associated with a process, activity, or program. That makes it difficult to determine whether the activity itself or the collaborative approach adopted to implement the activity that was responsible for the results obtained.

School Culture Supportive of Collaboration

Another factor contributing to or detracting from the growth of collaborative applications is school culture. Although nearly every school leader would profess to embrace collaboration and foster its development, data suggest that the words are not always accompanied by actions. In some schools, professionals are rewarded for their individual efforts with little attention paid to collegial work. In yet others, leaders tend to use a directive style that causes teachers and other personnel to isolate themselves, completing assigned tasks but avoiding commitment to shared work. In the US, such cultures sometimes are an unintended consequence of the current trend toward individual educator accountability for student academic achievement as measured on standardized high stakes assessments.

Professional Preparation for Collaborative Responsibilities

Whether an individual professional is prepared at the preservice level for the collaborative activities they are likely to experience in schools depends in large part on the approach taken by the preparation program they completed. Most special education personnel are required to take coursework on collaboration and have intensive field experiences with teaming and co-teaching. A similar comment could be made for middle school teachers and team teaching. However, elementary and high school teachers may or may not have any direct preparation related to collaboration. If they do not, the consequences may be sobering. These educators may find an expectation for collaboration as foreign and potentially intrusive. They may be resistant to the notion of sharing responsibility and accountability, and most of all, they may lack the skills for effective collaborative practice, including communication and problem solving skills, which, in turn, may limit outcomes for their students.

The Logistics of Collaboration

In too many schools, even when commitment to collaboration is strong, professionals understand and welcome collaborative roles, and school leaders encourage collaborative practices, those practices occur only informally or on a significantly limited basis. The reasons too often relate to logistics. One issue may be time available for professionals to work with one another in any other than a superficial way. That is, school schedules may not incorporate time for professionals to regularly work together, and times before and after school may be filled with other responsibilities and meetings. Teachers may perceive that they do not have sufficient time to adequately discuss problems and may feel pressure to find solutions regardless of the insufficient analysis of them (Williamson and McLeskey, 2011). Further, specialists such as data or behavior experts, may not be available to attend meetings at times convenient for teachers, and the teachers have to proceed without potentially valuable input. The result can be interventions or solutions that are not effective.

A second example of logistics challenges concerns physical space, which may affect the feasibility, structure, and character of collaboration. Professionals need appropriate settings for their collaborative efforts, whether that is a classroom for co-teaching or team teaching or a safe and private conference room for consultation or professional learning communities. When reasonable space cannot be provided, problems can occur. For example, a group trying to find a solution to a problem left to work in a library where students and other staff roam may be less likely to speak freely and record their ideas on a chart due to confidentiality concerns. This may disrupt the group's brainstorming, resulting in dissatisfaction on the part of participants and planned interventions that may not be the product of the group's best thinking.

Conclusion

Collaboration, as understood in a technical professional sense, is essential in contemporary schools and is a reflection of the trends toward shared work in other disciplines, including business and medicine. Examples of collaborative applications include teaming, professional learning communities, consultation, co-teaching, team teaching, school–agency, and school-to-school collaboration. And even more examples could have been described, including the collaboration that school professionals have with parents and family members, the partnerships that exist between schools and universities, and projects that emphasize collaboration between schools and community organizations. As expectations continue to increase for student achievement and educators are faced with increasingly complex job demands, collaboration likely will continue to blossom as a vehicle through which higher student achievement and other positive student outcomes can be obtained.

Abstract

How strongly does a student's cognitive and motivational development depend on various characteristics of schooling? This article describes the origins and developing profile of the field of research on differential effects of learning environments, the current knowledge about central characteristics of schooling, persistent methodological challenges, and implications for educational practice.

How much difference does it make for math achievement if one has the best math teacher in the best school of town rather than an average teacher in a typical school? How strongly is a student's motivation affected by the students she or he is studying with? These and similar questions are extremely important issues – for both research and practice. Millions of parents around the world think about these issues when they make decisions about their children's school biographies, and an increasing number of researchers from several different disciplines are busy in finding adequate ways of gauging the effects of schooling.

In examining "effects of schooling," it is important to distinguish between two perspectives. When school versus no school conditions (e.g., "is there an effect of two more years of schooling on cognitive development?") are compared, one studies 'general' or 'average' effects of schooling on cognitive or motivational development. When differences among classes, tracks, schools, school systems, and the like are studied (e.g., "how much difference does school quality make?"), the primary focus is on what we will call "differential effects of learning environments." Learning environments such as school classes, schools, or school types function as differential learning and developmental environments "when young people – independent of, and over and above, their individual intellectual, cultural, social, and economic resources – are afforded different developmental opportunities" depending on the class, school, or school type they attend (adapted from Baumert et al., 2006, p. 99, own translation). This article focuses on the emerging field of research on differential effects of learning environments as evidenced in large-scale school achievement studies.

Schools as Differential Learning Environments: The Emergence of an Interdisciplinary Research Field

The starting point of modern empirical research on the impact of schooling on children's development is typically seen as back in the 1960s when the Coleman report (Coleman et al., 1966) was published and the International Association for the Evaluation of Educational Achievement (IEA) conducted its first study comparing the academic achievement of 13-year-olds in 12 countries (Foshay et al., 1962). Since these pioneer studies, empirical research on the impact of schooling has increased tremendously – not only with respect to national studies, but also regarding large-scale cross-national studies: The IEA now conducts several studies with up to 60 participating education systems. The Organization for Economic Development and Cooperation (OECD) has started its own Programme for International Student Assessment (PISA) in 2000 involving more than 70 countries to date. The increasing breadth of the data base also concerns the variables under study. Whereas earlier studies on the effects of schooling (including international school achievement studies) had their main focus on students' academic achievement, in the last two decades students' motivational development and their engagement in learning have become a key focus of empirical studies on the impact of schooling.

From its beginning, research on the effects of schooling has been a field that attracted researchers with diverse disciplinary backgrounds, and this multidisciplinary background has contributed to the richness of conceptualizations of the effects of schooling. As observed by Wang et al. (1993), researchers from different disciplines typically had a focus on different variables. For instance, sociologists were usually concerned with demographic variables such as social class as well as institutional differences between schools. Political scientists studied the impact of federal, state, and district policy variables. Psychologists typically studied individual characteristics of teachers and learners and the interactions between them. Adding to that list, pedagogical research concentrated on the aims of schooling and the design and content of curriculum.

Over the last two decades, new developments can be observed with regard to the disciplinary composition of research on the effects of schooling. Additional disciplines have increased their efforts in this field, making the field more heterogeneous. Notably, economics of education has attracted much interest (e.g., Hanushek et al., 2010) and brought in a focus on efficiency and the so-called 'returns to education' (the monetary exchange value of education). Moreover, the field of didactics has become more important, specifically when explaining domain-specific outcomes of teaching. In addition, the construction of standardized achievement tests and decisions about research designs has increasingly been informed by psychometricians. Although currently more

focused on learning processes rather than learning outcomes, the emerging field of 'neuroeducation' might also contribute to research on the effects of schooling in the future.

On the one hand, these developments have added additional perspectives and methodologies to the study of the effects of schooling; on the other hand, they have helped to move toward more integrative frameworks that bring together the wisdom from various disciplines. In fact research on schooling effects (and, more broadly, effects of educational institutions) has become an interdisciplinary field in itself, to varying degrees across different countries, which brings together different streams of theorizing from disciplines such as educational research, psychology, sociology, economics, statistics, and others. In some countries, the interdisciplinary endeavor to study effects of schooling has become a separate discipline in its own right.

Integrative frameworks on the effects of schooling come in different forms. The so-called Educational Effectiveness Models (Creemers, 2009; Scheerens and Bosker, 1997; Wang et al., 1993) integrate the wisdom from various disciplines by systematically collecting variables at various different analytical levels with potential effects on academic outcomes and gauge their relative effect. For instance, in the theoretical framework by Wang et al. (1993) 228 variables are grouped into six broad theoretical constructs. The six theoretical constructs used to organize the framework are (1) State and District Governance and Organization; (2) Home and Community Educational Contexts; (3) School Demographics, Culture, Climate, Policies, and Practices; (4) Design and Delivery of Curriculum and Instruction; (5) Classroom Practices; and (6) Student Characteristics. The prominent overview study by Hattie (2009) on the most important determinants of academic achievement is also rooted in this tradition. A second form of integrative frameworks describes the process of learning and development as an interplay of individual characteristics and learning environments whose form may be different across different ages, schools, and school systems ("differential learning and developmental milieu" or "schools as multilevel social organizations"; Baumert et al., 2006; Eccles and Roeser, 2011). This second form of integrative models is typically less exhaustive in terms of variables, but rich in its theoretical foundation and more specific in explaining learning processes and the development of achievement and motivation.

Effects of Schooling: Early Findings and Current Wisdom

To the shock of many politicians, educators, and teachers, the influential Coleman Report (Coleman et al., 1966) concluded "that school brings little influence to bear on a child's achievement that is independent of his background and social context" (p. 325). Along similar lines, Jencks et al. (1972) stated a few years later "that the character of schools' output depends largely on a single input, namely, the characteristics of the entering children. Everything else – the schools' budget, its policies, the characteristics of the teachers – is either secondary or completely irrelevant" (p. 256).

The early accounts of the effects of schooling are likely to have underestimated the role of differential learning environments for several reasons. First, reading competence was the most important outcome in the Coleman report. However, as is known by now, differential learning effects in reading are smaller than in, for instance, mathematics. Second, the sample of schools used in the Coleman report was less diverse than it could have been, and this might have led to the observation of smaller effects. It should also be noted that the understanding of what is to be considered a small/meaningful effect has changed over the years.

In contrast to the earlier studies, contemporary wisdom on the effects of schooling emphasizes systematic differences in cognitive and motivational outcomes that can be traced back to differential schooling quality. At the same time, recent research clearly highlights the need to differentiate between various factors at several levels, different domains, and multiple outcomes when gauging the effects of schooling. The main findings from recent research on the impact of schooling on children's cognitive and motivational development are summarized next.

Differential Impact of Schooling on Cognitive Development

Schools are expected to teach students knowledge and skills in a number of different subjects, such as languages, mathematics, or science, which students need in later life. In recent years, both in practice as well as in research, there has been a shift in the educational objectives of schools. Whereas the focus used to be on the acquisition and reproduction of subject-specific knowledge, students are now expected to "apply knowledge and skills in key subject areas and to analyze, reason and communicate effectively as they pose, interpret and solve problems in a variety of situations" (OECD, 2010a, p. 18).

Against this backdrop, the concept of competence – similar to the concept of literacy used by the OECD and the IEA – has become prominent in studies assessing the impact of schooling on cognitive development. Competencies can be defined as context-specific cognitive dispositions for achievement which are acquired through learning and are needed to successfully cope with situations and tasks in specific domains (Klieme et al., 2008). In most studies on the impact of schooling, domain-specific competencies such as reading literacy, mathematical competence, or scientific competence are assessed. Whereas competence tests used in national studies focus more on specific school subjects and usually have higher curricular validity (therefore oftentimes called 'academic achievement tests'), the assessment of more broadly defined key competencies such as problem-solving skills or information and communication technology (ICT) literacy in addition to subject-specific competencies is becoming increasingly important in international large-scale assessment studies.

Characterized by its context specificity and its focus on 'real life' situations, the concept of competence is to be distinguished from general cognitive abilities such as intelligence. The concept of intelligence refers to the "relatively decontextualized ability to reason and to address new problems without content-specific knowledge" (Baumert et al., 2009). Whereas competencies have to be acquired through learning, intelligence can be learned only to a certain extent and is usually understood as a relatively stable characteristic of a person. In that sense, intelligence can be seen as an important determinant of the

development of domain-specific competencies (Baumert et al., 2009; Klieme et al., 2008). Even though intelligence is, consequently, oftentimes used as a predictor or a control variable in studies investigating the impact of schooling on students' competence development, there is evidence showing that intelligence is also affected by schooling (Becker et al., 2012; Ceci, 1991). However, in the following, we will focus on empirical studies investigating schooling effects on students' academic competencies.

How large are differences in students' competencies across schools and school systems? When comparing different countries in cross-national studies as those conducted by the IEA or the OECD, massive effects of the quantity and quality of schooling can be ascertained, in particular when comparing developed countries with developing countries. In PISA 2009, for instance, the gap in reading literacy between the highest and the lowest performing country was 242 score points, which is the equivalent of more than 6 years of formal schooling (OECD, 2010a). Similarly, in within-country analyses, substantial differences between mean scores in the best-achieving schools and the worst-achieving schools can be observed. In addition, even when controlling for differential intake (e.g., prior achievement and social background of students), longitudinal studies document substantial differences across schools and classes in cognitive development.

What aspects of schooling lead to these observable differences? In the classic review by Wang et al. (1993), "the theoretical construct with the greatest effect was Student Characteristics, followed by Classroom Practices, and Home and Community Educational Contexts. Having less effect were Design and Delivery of Curriculum and Instruction and School Demographics, Culture, Climate, Policies, and Practices, while State and District Governance and Organization had the least effect" (p. 270). This main conclusion is also echoed in more recent accounts. Drawing on Hattie's (2009) extensive synopsis of empirical findings on what affects students' academic achievement, which is based on over 800 *metaanalyses*, as well as other research reviews on what constitutes student learning (e.g., Eccles and Roeser, 2011), there is now a large consensus among educational researchers that proximal variables such as the instructional quality provided by the teacher exert a much stronger influence on students' competencies than distal variables such as school resources. Or put differently, general characteristics of the school environment do not necessarily impact student learning, they only do so when they reach down to the classroom level and affect teachers' instructional practices. This general result will next be illustrated with respect to three frequently discussed aspects of schooling (school resources, tracking effects, and teaching quality).

School resources: One characteristic of schools, which is often subject of many debates among parents, teachers, and policy makers, is the amount of resources available. Overall, the combined effects of resources are often overestimated (Hanushek and Lindseth, 2009). Whereas few researchers would argue that money does not matter at all, its impact clearly depends on the way it is spent. For instance, if a school uses additional resources to hire qualified teachers, the positive effect that school resources can have on student outcomes is evident. On the other hand, using more resources to reduce class size is not by itself going to have a positive impact on student outcomes; its impact depends on the instructional quality provided. Merely reducing the number of children in a learning group does not necessarily lead to different and more effective instructional strategies of teachers (for a summary, see Hattie, 2009).

Tracking/composition: Another practice in many school systems around the world is tracking, that is grouping students into different courses, study programs, or schools according to their achievement. Even though a large amount of research has been conducted on the effects of tracking on students' achievement in recent years, few strong and definitive answers have emerged. One general conclusion, which can be drawn, is that grouping students by ability has an effect insofar as it determines the curriculum and instruction students receive and exposes them to different peers. More specifically, it has been shown that students in higher tracks may develop higher competencies than students in lower tracks because they receive a different type of instruction and curriculum. Tracking also exerts an effect on students' competence development by determining the composition of the student body. There is strong evidence showing that being surrounded by high achieving students has a positive effect on students' competence development. But not only the mean achievement level of a school or a class is of importance, the social and – to a lesser degree – the ethnic composition of the student body has also been shown to impact students' learning: As the ratio of students from disadvantaged families goes up, the achievement of students goes down. These effects of the composition of the student body are again assumed to be mediated by more proximal variables, such as teachers' practices and daily interactions between students. To that effect, the composition of the class has a greater influence than the composition of the school.

Teaching quality: Generally, the instruction a teacher provides needs to be intellectually challenging and cognitively stimulating for students by paying close attention to the prior knowledge of students (Kunter et al., 2013). This may be achieved by many different practices and strategies such as cooperative learning, direct instruction, concept mapping, reciprocal teaching, or formative assessment. Whatever may be the specific strategy, close attention must be paid to the domain specificity of the competence that is to be learned. At the same time, teachers need to transport clear guidelines, communicate their expectations, and provide students with regular feedback. It is evident that this kind of instruction can be more easily given by teachers who have higher levels of teacher qualifications, more knowledge in the subject matter as well as more pedagogical content knowledge. But not only characteristics of the teachers themselves are important, there is also evidence showing that principals or school leaders may play an important role in the development of students' competencies when they show strong instructional leadership, including a learning climate free of disruption, a system of clear teaching objectives, and high expectations for teachers and students.

Impact of Schooling on Motivational Development

A positive development in motivation is seen as both a goal of schooling in itself and a strong determinant of academic

achievement and students' educational choices. Whereas student motivation was understood to be externally driven within the behaviorist tradition of the early twentieth century, current theorizing understands student motivation as a social-cognitive process. Student motivation is, thus, determined by students' subjective beliefs and attitudes toward schooling, which are developed in response to their social surroundings. Motivation has more stable and more variable, that is more situation-specific, elements. Because of space restrictions, our emphasis in this article is on interindividual differences in relatively enduring motivational predispositions to engage in academic activities. Pintrich (2003) differentiated among five central motivational constructs: competence beliefs, control beliefs, interest, value, and goals. This article exemplarily focuses on two of these constructs – competence beliefs and value – which have been prevalent in motivational education research in the last few decades.

Students' self-beliefs about their own abilities, capabilities, and competencies in certain areas, such as specific subjects and tasks, do influence the strength of their engagement with these specific tasks. The higher students' subjective expectancies to successfully engage in and master a specific situation are, the stronger their motivation will be to engage in this specific situation will be. Similarly, students' motivation to engage within the school context is seen to depend on the extent to which the specific context matches their values, needs, and goals. In addition, the subjectively perceived usefulness of a specific task in terms of accomplishing one's personal goals and the perceived enjoyment while performing that task is seen to increase the likelihood of students' engagement (Eccles and Wigfield, 2002).

Summarizing a huge number of studies, several characteristics of the learning environment are substantially associated with motivational development. As with achievement, classroom processes are closely associated with motivational development, whereas somewhat 'paradoxical' effects are found at the level of schools/tracks.

Tracking/classroom composition: The composition of the student body with regard to its academic achievement levels has been found to be one important contextual influence. In particular, students' self-beliefs about their ability are strongly affected by the achievement levels of their immediate classmates (Marsh et al., 2008). When assessing their own abilities and academic standing, students will naturally use the achievement levels of their immediate classmates as a frame of reference. Thus, equally able students have been found to report lower confidence in their academic competencies if they are attending schools with higher average levels of ability, a phenomenon that is commonly described as the big-fish-little-pond-effect. Further research suggests that students' valuing and enjoyment of school, e.g., their interests, might potentially be affected in a similar way. Selective schooling thus might produce negative motivational patterns for students of high ability. To fully depict the complexity of the influence of peers' ability levels on individual student motivation, however, the type of ability tracking needs to be taken into account as well (Chmielewski et al., 2013).

Teaching quality: The type of classroom environment that is created by teachers has been shown to be particularly influential to the development of student motivation. Teachers influence the development of student motivation in multiple ways within the classroom setting: through their choice of tasks and materials, the instructional practices they employ, and the type of relationship they foster with their students (Schunk et al., 2008). With regard to the choice of tasks and materials, certain task characteristics have been identified to be beneficial for the development of student motivation. The use of surprising task features, the use of challenging tasks in combination with appropriate instructional support as well as highlighting the relevance of the educational content for students' lives appear to positively influence students' enjoyment, their feelings of competence, and the value they attach to school. Considering teachers' instructional practices in the classroom, several instructional practices have been identified that promote student motivation in the classroom. On the one hand, the application of student-centered classroom practices that support students' feeling of autonomy such as the provision of choices has been shown to increase student motivation and engagement in the classroom. Additionally, teacher practices that support students' feelings of competence such as the provision of informative and constructive feedback that focuses on students' individual improvement over time will increase student motivation. At the same time, teachers' general classroom management influences student motivation. The use of proactive practices such as communicating clear expectations and rules with regard to classroom conduct has been shown to support students' commitment and attachment of value to school. Lastly, the type of relationship that teachers foster with the students in their classroom is connected to the development of student motivation (Wentzel, 2009). The provision of an emotionally safe and trusting environment in which teachers act as role models as well as confidantes providing social support has been found to increase student commitment and valuation of school. A supportive relationship with the teacher appears to be instrumental for student motivation over and above the support that is provided by parents and peers in some circumstances.

Interest differentiation: Schools are sometimes seen as a killer of student interest rather than a developer (Travers, 1978, p. 125). In fact, the trajectories for motivational dispositions such as self-concept and interest show a decline from school entrance to adolescence, and this decline might be particularly strong under some conditions. For instance, it has been suggested that the decline in student motivation from elementary to secondary schooling commonly found in national and cross-national studies is actually related to systematic changes in the classroom environment. It is assumed that the classroom environment in secondary schools fails to meet the specific developmental needs of students (Eccles et al., 1993). Students' increase in self-awareness and their increased need for independence during adolescence appear to be mismatched with the organization of the classroom environment that is shaped by a high level of control and promotion of social comparison and competition within secondary schools. At the same time, the overall decline in self-concept and interest may also reflect age-normative developmental trends in terms of intraindividual differentiation across different subjects: Although students partly lose interest in some or the majority of their subjects, most students have stable or even increasing interests in other subjects.

Persisting Methodological Challenges

Because of several methodological challenges, it is too early – and in fact impossible – to make final statements about the size of the effects of differential learning environments. First, it is quite obvious that the size of these effects differs across different samples; for instance, between-school differences may tend to be larger in more differentiated school systems. Moreover, the size of effects is likely to change over time as school environments and societies develop. Second, the outcome variables under study also determine the observed effects (for instance, larger effects have been found for mathematics than for reading). Third, a fundamental challenge for research on schooling effects are problems with 'differential intake' or 'selection.' In order to come to an accurate estimate of the impact of a certain aspect of schooling (such as the composition of the student body of a school) on students' competencies, there is a need to (statistically) control for other variables affecting student outcomes, most importantly students' family background and characteristics of students such as intelligence and their prior knowledge (Scheerens and Bosker, 1997). Unfortunately, not all empirical studies control for these variables when analyzing the impact of schooling on students' cognitive development. Experimental and quasiexperimental intervention and reform studies are still rare. Fourth, measurement issues are relevant because the restricted reliability and validity of some achievement tests will lead to a downwardly biased estimate of schooling effects. Fifth, there are a number of challenges for data analysis including the handling of hierarchically structured data and the almost inevitable problem of missing values that have not been overcome in a satisfactory way; missing values are particularly troubling if there are differential participation rates/differential attrition across different learning environments.

Practical Implications

How can current research findings on the effects of schooling inform educational policy and practices? First, the research findings which indicate that students' development differs to a meaningful degree depending on the learning environment they experience highlight issues of distributional justice. Differential outcomes despite similar initial student characteristics are at odds with meritocratic principles embraced in many societies. In fact, in many countries there is the explicit goal and widespread claim that all schools are of comparable quality so that, in general, there are no – or only small – differential effects of schooling, and student development is believed to be similar across different learning environments. In a less strict variation of this approach, in some countries with a rather differentiated school system, it is claimed that although schools differ in some respects, each student is assigned to a school that offers a perfect fit for his or her strengths and needs. At first sight, differential effects of schooling are less of a normative problem in school systems in which differences in cognitive and motivational development as a consequence of differential learning environments are considered to be in line with meritocratic principles because the placement in 'good' schools is believed to depend on prior achievement and/or student aptitude; however, research findings may not unanimously support these claims and thus challenge policy practices in providing each student with equal opportunities.

A second implication of the evidence for the existence of differential learning environments is that in most school systems there is considerable room for improvement. Intervening with crucial determinants of cognitive and motivational development will likely have a positive impact. For instance, if all schools within a state became as effective as the most effective schools within this state, the average achievement in this state might increase considerably, especially if their effectiveness was quite different in the beginning. Along these lines, ways to improve the quality of schooling have been discussed in many countries, and several measures have been put in place. An influential, well-known example from the recent past is the No Child Left Behind Act of 2001 in the US which is often referred to as a highly ambitious perspective on how much improvement in educational effectiveness is possible over a short timeframe. For instance, one element of this act is the Adequate Yearly Progress (AYP) in test scores on standardized achievement tests that schools need to 'produce' in order to receive federal funding. However, current research does not unanimously support the optimistic view on how much progress can be achieved over a relatively short time span as formulated in this and similar reforms. Importantly, unlike less important factors such as class size and the use of tracking, the most powerful determinants of student achievement are not easily influenced by political interventions. For instance, teaching quality cannot quickly and easily be increased, but rather requires long-term efforts to increase the quality of teacher education and to attract the best candidates to the teaching profession. Moreover, research highlights the fact that – given the huge selectivity effects in school composition – even schools with below-average student achievement can be very effective schools (and therefore may not have much room to improve).

Future Directions

Whereas current research allows for a general understanding of the sources of differential cognitive and motivational development, there is a need for ambitious research programs that lead to a better understanding of schooling effects. For instance,-more research is needed to understand the seemingly opposing effects of classroom composition on cognitive and motivational development. Moreover, the strength of the association between proficiency and motivation varies considerably between countries, which suggests potential differential influences of the school system on student motivation across different countries. Similarly, we have yet to better understand how student characteristics may moderate the effects of characteristics of the learning environment (i.e., there is a lack of systematic studies of aptitude–treatment interactions). In addition, there is a need for more intervention work. Intervention studies are particularly strong in terms of establishing causality and could also help in finding ways to positively impact students' cognitive and motivational development. More generally, rather than just 'predicting' cognitive and motivational development, there seems to be a need for longitudinal studies with a broad theoretical background encompassing the

wisdom of several disciplines in order to better understand the processes underlying cognitive and motivational development. Longitudinal studies will also help to understand the long-term impact of schooling (mediated by cognitive and motivational development) on lifelong learning, educational attainment in higher education, and active participation in society.

Schooling: Total Impact of

Hans Luyten, Faculty of Behavioural, Management and Social Sciences, University of Twente, Enschede, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The total effect of schooling on the cognitive development of young people (its prime objective) has been addressed in a remarkably small number of studies. The available findings indicate that at least 50% of the learning gain across grades can be attributed to the effect of schooling. This figure contrasts sharply with the more frequently cited 'school effect' of only 15%. Some additional questions remain to be settled: for example, to what extent the impact of schooling varies across age ranges, content areas (e.g., language vs mathematics), background (e.g., by socioeconomic status or gender), and (last but not the least) across schools.

Introduction: The Importance of Schooling

Young people spend many hours in school. Thus it seems plausible that the impact of formal schooling on their cognitive development is considerable. However, one cannot assume that all progress made during the school years is due to formal schooling; for example, during their years at primary school children grow approximately 6 cm in length per year, but it seems hardly plausible that classroom instruction has any impact on this growth. In contrast, some cognitive skills developed during the school career are probably acquired in large part through classroom instruction (e.g., spelling and arithmetic), but other skills (e.g., vocabulary) may largely be learned outside school.

The theoretical underpinning of the presumed benefits of education (for personal income and nationwide economic growth) largely stems from the work by human capital economists (e.g., Becker, 1993). In human capital research the results of education are typically measured as qualifications attained or amount (i.e., years) of schooling received. Research in this field strongly focuses on the relationship between academic credentials and success on the labor market. The number of empirical studies that explicitly address the impact of formal schooling on the cognitive development of students (its prime objective) turns out to be surprisingly small.

One might expect to find extensive information on the impact of formal education on cognitive skills in the research literature on educational effectiveness. However, this line of research has traditionally focused on comparing schools, classes, and teachers and has yielded a considerable knowledge base on the variation between schools, classes, and teachers with regard to the outcomes of learning. More importantly, it has produced useful insights on the factors that may account for this variation and provide levers for improvement (Teddlie and Reynolds, 2000). However, assessing the impact of education on the development of children in its own right has never been an issue of major concern in this field.

A well-confirmed finding in educational effectiveness research is the percentage of variance in student achievement scores at the school level. This is usually referred to as the *school effect* and has been found to equal 15% on average over a huge number of studies. It is important to note that this school effect relates to differences in outcomes between schools. It is perfectly conceivable that all schools make a similarly large contribution to student development. This would produce a modest school effect even though the *total effect of schooling* is considerable.

Assessing the Total Effect of Schooling – Two Viable Alternatives

When trying to assess the contribution of schooling to the development of students, one is faced with the challenge that nearly everyone attends school. In order to estimate the contribution, one should compare those who attend school to an equivalent control group that receives no schooling, which is not feasible in practice. Ceci (1991) has reviewed a number of methods that may be helpful in assessing the impact of schooling on cognitive development. Most of these capitalize on exceptional circumstances, for example, (temporary) absence of schooling in remote communities, interrupted schooling during times of war, and changes in mandatory schooling. Studies based on these methods provide compelling evidence for a strong impact of schooling on the development of cognitive skills. Needless to say, such methods cannot be applied on a routine basis.

Regression Discontinuity

According to Ceci (1991), one of the best ways to document the impact of schooling is by comparing children of the same chronological age in different grades. This can be done by applying the logic of the regression-discontinuity design (Trochim, 1984). It capitalizes on the fact that assignment to grades is mainly determined by date of birth. In most education systems, students born just a few days before a certain cut-off date are much more likely to end up in a higher grade than the ones that are just a little younger. Such cut-off dates are clear examples of instrumental variables (Angrist and Pischke, 2009). They affect the score on the explanatory variable of interest (i.e., grade), but are not causally related to the outcome variable. Instrumental variables are sometimes said to produce 'natural experiments.' Thus they allow for unbiased estimates

of the effect that is the focus of the analysis, even when data on confounding variables are not available.

Application of regression discontinuity requires hardly any background information of the students. Besides measures of learning outcomes (e.g., test scores), information on each student's date of birth and actual grade are needed. Two final requirements are that the dataset should relate to students in adjacent grades and that the outcome measures should relate to a common scale, even though the students are in different grades. When students from a wide range of grades (e.g., grades 1–6) are included in the analysis, one cannot expect all students to take the same tests, but this problem can be solved by making use of equated test scores so that all scores can be expressed on a common scale (Verhelst, 2010).

It is also necessary to reflect on the meaning of the effect of education as assessed through regression discontinuity. The effects estimated actually reflect the difference in achievement due to assignment to a higher or lower grade. It should be acknowledged that this possibly includes components that may not be considered effects of education in a more narrow sense. For one thing, the grade effect will also include a peer group effect. It is also conceivable that parents make adaptations in the way they support their child when (s)he is assigned to a higher grade. It should be noted, though, that all these effects are *caused* by assignment to grades. In that sense they still are effects of schooling. However, one may consider these as side-effects of schooling rather than its core effects.

Seasonality of Learning

If one assumes that during the school year learning gain is affected by both school and nonschool factors, whereas only nonschool factors are at work during the summer vacation, the effect of schooling can be estimated by means of a comparison between the per month learning gain during the school year and the summer vacation (Heyns, 1978). Although this approach seems useful for estimating the total effect of schooling, it is also important to point to some problems.

The main problem relates to the assumption that the summer period presents a useful alternative for the control condition in a randomized trial. This is valid if we can be sure that the impact of nonschool factors (e.g., parental support) during the summer vacation provides a reliable indication of their impact in the (hypothetical) absence of schooling, but it is conceivable that certain parents (e.g., the well-educated ones) engage more in academically stimulating interactions with their children than they would otherwise during the summer vacation. It remains an open question whether the summer period presents an equally viable alternative for a control condition for all students. Another implicit assumption of the approach is that the effect of schooling stops as soon as the summer vacation starts. Most teachers would hope that their efforts have a more enduring effect and that learning still continues out of school due to their teaching efforts.

The main focus in seasonality research has been on the summer gain/loss itself and particularly on inequalities in this respect. The bulk of the studies have been conducted in the USA (probably because of the long summer vacations).

Findings

Numerous studies on the seasonality of learning have consistently shown much stronger gains during the school year than during the summer vacation. Sometimes zero learning gains and learning losses have been reported for the summer period. A consistent finding is the large variation in learning gains during the summer vacation. When school is in session, the differences in cognitive growth between students are much smaller than during periods without schooling. Especially students from disadvantaged backgrounds appear to make relatively little progress during the summer period. This suggests that education presents an equalizing force of considerable importance (Downey et al., 2004; Alexander et al., 2001).

The number of studies based on regression discontinuity is much smaller, but these studies focus explicitly on the total effect of schooling. One of the first well-known studies was conducted by Cahan and Davis (1987) and relates to mathematics and reading comprehension in grades 1 and 2 of primary education in Israel. The findings indicate that about $^{2}/_{3}$ of the difference in achievement between grade 1 and 2 students is due to schooling versus $^{1}/_{3}$ due to the 1-year difference in age. A study using the same approach to assess the impact of schooling on IQ development of Israeli children in grades 4 to 6 (Cahan and Cohen, 1989) reports larger effects for verbal than nonverbal tests. It relates to 12 different tests and for nine of these the effect of schooling outweighed the age effect.

A more recent study by Luyten (2006) applied regression discontinuity within a multilevel framework in a secondary analysis of TIMSS-95 data (http://timssandpirls.bc.edu/) for eight different countries. The effect of schooling on mathematics achievement in grades 3 and 4 of primary education was modeled as random at the school level. This approach yields both an assessment of the average effect of one year of schooling and an estimate of its variation across schools. In line with the Israeli studies, this study reports larger effects of schooling than age in most countries. It also reveals that in most countries a substantial minority of schools could be discerned that failed to show a positive effect of being in a higher grade (4 vs 3).

Most studies based on regression discontinuity assume a sharp cut-off date, which implies that students with delayed or accelerated school careers are excluded from the analyses. A study by Luyten and Veldkamp (2011) applies a methodology that does not assume a sharp cut-off date and takes into account the effect of unmeasured factors that affect both learning outcomes and assignment to grade (i.e., delay or acceleration of school careers). Their reanalysis of TIMSS-95 data includes 15 countries. They report that for mathematics and science, respectively, 54% and 47% of the differences between grades are due to schooling. When expressed as an effect size (Cohen's d), the average effect of grade level across 15 countries is 0.46 and 0.35 for mathematics and science, respectively. By themselves these are not particularly large effect sizes, but if they apply to all grades in primary education, the total effect for all six grades would fall between 2.00 and 3.00, whereas 0.80 is generally considered a very large effect.

Concluding Remarks

Although the total effect of schooling on the development of students has been the explicit focus of a limited number of studies, there can be no doubt about its impact. The effect of schooling appears to be clearly stronger than the effect of physical maturation and at least half of the cognitive growth that occurs during primary education should be considered an effect of schooling. This implies that the effect of schooling is much larger than the 'school effect' (i.e., 50% vs 15%). The latter relates to differences in outcomes between schools. Studies on the seasonality of learning suggest that formal education works as an equalizing force. Disparities in knowledge and skills tend to widen mostly during periods when school is not in session.

Nevertheless some additional questions remain to be settled. It is unclear to what extent the effect of schooling varies over different age ranges. It seems likely that the effect of age decreases as children grow older. How far this applies to the effect of schooling is still an open question. Whether the effect of schooling differs for students from various backgrounds (e.g., low vs high SES) has hardly been addressed, although the findings from seasonality of learning suggest that the effect is similar for all students. Last but not the least, little is known about the variation of the effect of schooling across schools. The only study that has addressed this issue (Luyten, 2006) suggests substantial variation between schools, even though the effect of schooling appears to be considerably larger than the school effect.

Schools in the Social and Behavioral Sciences: Concepts and Historical Relevance

Christian Dayé, University of Graz, Graz, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The term 'schools' in social and behavioral sciences (SBS) refers to two different types of concepts: the school of thought, which consists mainly of a coherent set of interrelated ideas and positions, and the concept of the school as institution, which takes in view not only a system of ideas, but also the social organization in which this system is developed and stabilized. The article introduces theoretical approaches to these concepts and discusses their relevance for the history of SBS. Both concepts of schools imply that SBS disciplines are not characterized by a consensus on theoretical and methodological principles, but must be conceived of as multiparadigmatic.

Introduction

A variety of ideas and concepts are associated with the notion of schools in social and behavioral sciences (SBS). Basically, the main thrust of all use of the term is to argue that a given field is not characterized by homogeneity as regards theory, methodology, or research practice. Instead, a variety of lines of reasoning, or paradigms, coexist under the umbrella of the discipline. This, in turn, implies that the intellectual development of a discipline or field at large cannot be understood as showing patterns of linear accumulation of knowledge. Rather, the intellectual development is a complex product emerging of the interplay between the schools in the field.

Four main concepts of schools in SBS can be discerned: (1) a typological, (2) a psychological, (3) an institutional, and (4) a concept of 'national schools' (cf Szacki, 1975).

The typological and the psychological concept can be seen as discernible though partly complementary dimensions of what is often called a 'school of thought'. (1) The thrust of a typological understanding is to classify scholars or scientists according to the ways they work and think, "independent of whether they maintained any contacts or not, and whether they would have themselves included in that particular 'school'" (Szacki, 1975: p. 176). (2) When, in contrast, a scholar or researcher defines himself or herself as belonging to a school of thought, we have an instance of a psychological concept of a school. The feeling of being not alone in following a certain set of ideas and convictions might have psychological benefits, even if the persons thus related never actually meet. Proponents of new approaches can draw profit from finding principles of their approach adumbrated or anticipated in the works of the founders of their disciplines. Such relations help to stabilize new approaches in the decisive early phases, mostly because they appear to justify the establishment of a new field within a discipline (or at its borders). For example, the references to Georg Simmel in the literature on social network analysis can be understood by the psychological benefits arising from defining oneself as member of an already existing school of thought, even if the person who formulated the school's basic tenets is long deceased. An interesting phenomenon is that in some cases, the psychological concept predated the typological. Bronisław Malinowski's invoking of a functionalist school in his early writings crucially contributed to functionalism becoming established typologically as a school of thought in SBS.

Opposed to schools of thought, more sociological or cultural uses of the term can be found in the historical literature. The main types here are (3) concepts based on an institutional argument and (4) concepts focusing on national schools. (3) Basically, an institutional concept of school implies that the "interests, assumptions, theses, etc., common to a given group of scholars are formed and consolidated within one institutional framework" (Szacki, 1975: p. 174). (4) To speak of national schools in SBS, finally, suggests that institutional and cultural environments within a nation fundamentally and crucially informed the basic tenets of a given discipline within this country. This concept implies that there is, to a certain extent, homogeneity within a discipline all across the country and that the links between the institutional and cultural habitat of a science within a nation-state and its theoretical and methodological peculiarities can be specified. Schools that at first sight appear as national schools, for instance the Austrian School in economics, might actually be better treated as schools of thought.

With regard to SBS disciplines and fields, the most relevant understandings of the notion of school were typological and institutional concepts. The following two sections of this article focus on these. An adjacent section focuses on the methodological implications of the discussed concepts in order to compare them to the neighboring concepts of invisible colleges (Crane, 1972), theory groups (Mullins, 1973), and academic tribes (Becher and Trowler, 2001). The concluding section attempts an outlook on the future of the various school concepts.

Schools of Thought

Characteristics

Speaking of schools of thought presupposes both an internal coherence and an external distinctiveness of their system of thought (Negru, 2013). Internal coherence refers both to the internal logic of a system of thought and to the homogeneity of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03010-5

the various contributions to this system, although the latter aspect should not be taken to say that there is no disagreement or conflict among various members of a school. Rather, homogeneity is a matter of degree. Furthermore, the system of thought must be sufficiently distinctive from other traditions. Such system of thought might comprise ontological, epistemological, methodological, ethical, and axiological, as well as ideological elements. The importance of a coherent and distinctive system of thought discerns schools of thoughts from the neighboring concept of the scientific community (Hagstrom, 1965).

Several sources might provide a school with a coherent and distinctive system of thought. One prominent source, and one close to the original meaning of the term 'school', is the teacher: an individual who developed a doctrine and is regarded as a model by his pupils. Durkheimian sociology is one example, Keynesian economics another. Another source is broad theoretical frameworks, like structuralism, functionalism, or symbolic interactionism. Further, research techniques and methods can also provide sufficient coherence and distinctiveness to become the intellectual core of a school of thought. It should be emphasized that schools of thought are not restricted to one field or discipline but can, like e.g., functionalism, spread across a variety of fields, and although the actual shape of the system of thought can show differences from discipline to discipline, the basic tenets can be broad and flexible enough to guarantee coherence. But that need not be the case: cross-disciplinary schools of thought can disintegrate into several disciplinary schools, if the differences among disciplinary proxies become too obvious.

How schools of thought are established and, conversely, why some schools of thought fail to do so are questions of vital relevance to the history of SBS. The second question has been explored by Neil McLaughlin (1998) with regard to Neo-Freudianism. Neo-Freudianism was a culture-oriented reformulation of Freudian psychoanalysis that emerged in the 1930s. In the following two decades, it became highly influential among both mental health practitioners and scientists from the SBS, but also left its imprint on the broader intellectual culture. But then, "attacks from members of the orthodox psychoanalytic establishment increasingly isolated" this line of thinking (McLaughlin, 1998: p. 113). Its influence declined, and by the 1980s, there was no Neo-Freudian school of thought. The failure of Neo-Freudianism to establish itself lastingly as a school of thought cannot be explored solely by personal differences between the main protagonists, Karen Horney, Erich Fromm, and Harry Stack Sullivan. Rather, the "goals, ideas, politics, and institutional and sociological positions of the major neo-Freudians were too different from each to make a school of thought possible" (McLaughlin, 1998: p. 128f.). The system of thought was distinctive, but not coherent enough. Its center was a sophisticated critique of Freudian thinking, which nonetheless did not lead to constructive theoretical or methodological developments that Horney, Fromm, and Sullivan could unanimously share. This was if not caused, then aggravated by the different positions the protagonists occupied – Horney being a therapist with "a proto-feminist bent", Sullivan a "brilliant and charismatic clinician […] who understood the importance of institution building and selling psychiatry to policymaking elites", and Fromm a "renegade sociologist and more of a prophetic figure than an academic expert or even a clinician" (McLaughlin, 1998: p. 129). Also, personal tensions among the proponents have played a role.

Historical Relevance

Assessing the relevance of schools of thought for the history of SBS is difficult because the answer must address both the levels of historical fact and of the historiography of a field. Some SBS disciplines show a tradition of producing textbooks that are organized along schools of thought in a typological understanding. This is most notably the case with psychology: taking E.G. Boring's *A History of Experimental Psychology* (1929) as their model, textbooks like Robert S. Woodworth's *Contemporary Schools of Psychology* (1931) and Edna Heidbredder's *Seven Psychologies* (1933) treated the field as organized into schools (cf Green et al., 2013: p. 168). Though not always with explicit use of the term, and sometimes in combination with topic-oriented chapters (e.g., Goodwin, 2012), the presentation of psychology as a multitude of mostly coexisting schools of thought – Wundtian experimental psychology, structuralism, functionalism, gestalt psychology, behaviorism, and so forth – has been an important pattern in psychology textbooks throughout the twentieth century. This also holds true with those SBS that are overtly multiparadigmatic, most prominently with economics (e.g., Dow, 1996; Mair and Miller, 1991; Snowdon et al., 1994), sociology (Martindale, 1960; Sorokin, 1928), and political science (Bleek and Lietzmann, 1999), and occasionally with subfields such as interpretive social research (Scott and Keates, 2001) or international relations (Thompson, 1996).

Schools of thought have thus been historically influential first and foremost as didactical devices that help beginners demarcate the field of study. Textbooks that are organized according to schools convey a mental map of the field, in which a small number of intellectual gravitational centers, usually not more than a dozen, are located. In theoretical and methodological debates in the classroom and beyond, schools of thought then function as a proxy for discursive positions that may help to clarify an argument. Major battles evolve around the inconsistencies and conflicts between schools and define a good part of the shape of the discipline or field.

Discussion

The criticism most often voiced against the use of the concept of schools of thought is that it is a Procrustean bed. It cuts off important differences and idiosyncrasies of authors in order to fit a banalized version of their thought into a predesigned scheme. (This charge has also been voiced against Nicholas Mullins' (1973) description of theory groups; see below.) The usefulness of such an artificial concept for historical analyses of the development of SBS has been disputed from a variety of methodological and theoretical orientations, and some authors sought to develop an institutional concept of schools to overcome the shortcomings of the concept of schools of thought.

Schools as Institutions

Characteristics

As a rule of thumb, an author refers to an institutional concept of school if the school's name includes the name of its location. To take only some examples from the history of economics, literature locates schools in Cambridge (Backhouse, 2006; Pasinetti, 2005), Chicago (Emmett, 2009; van Overtveldt, 2007), Kiev (Sušjan, 2010), and Stockholm (Erixon, 2011), among other places. Of course, the degree to which each of these conforms to the criteria of an institutional concept must be established by detailed analysis, and this requires a workable conceptualization of schools as institutions. Most conceptual work in this area comes from sociology, with other SBS disciplines contributing to it.

One of the most elaborated conceptualizations of schools as institutions has been proposed by Edward A. Tiryakian (1979). A school consists of people who are in relatively close contact to each other and form "a real group of intellectuals, a small community of persons whose origin and formative period can be localized in time and place" (Tiryakian, 1979: p. 216). Sociologically speaking, they share several characteristics with religious communities. The basic differentiation within a school is between a founder-leader and his followers, who are committed to the doctrines of the founder-leader and united in the mission of establishing them. This hierarchy discerns schools from formally more egalitarian collaborative circles (Farrell, 2001). The founder-leader has developed to a certain point a system of thought, and against the orthodoxies and established views of the field, he or she believes in the value and viability of his or her system. Usually, he or she is a charismatic person, a fact that further strengthens the commitment of the followers. Schools as institutions thus are a collective and mediating entities located between the individual researcher and the scientific community.

Among the followers, various roles can be discerned. One of these is the interpreter. "Very often, the founder-leader is one who, because he has such an intense, innovative way of conceptualizing the reality of the world, has trouble expressing himself in ordinary language" (Tiryakian, 1979: p. 219). To convey the message in a way accessible to those not so close to the founder-leader becomes the task of the interpreter, or popularizer. A second role is the pragmatic organizer, who takes care of the school's day-to-day activities. A further group of followers potentially decisive for the success of the school are the converts, scholars who received their training elsewhere (and might thus have the same age as the founder-leader) but later became convinced of the surpassing quality of the founder-leader's worldview. Their contacts to the field outside the school can prove vital in disseminating its doctrines. Another crucial group are the students, or lieutenants, some of whom might become the leaders of the school after the departure of the founder-leader and the converts, from whom they take over the task of promoting the institutionalization of the doctrine in the discipline at large. Further positions include the auxiliary, a 'loyal foot soldier' assisting in promoting the school's visibility, but without any original intellectual contribution; the patron, who does not fully participate in the intellectual debates within the school, but provides material and financial assistance; and the confidant, an individual personally close to the founder-leader who provides emotional, but not intellectual, support.

Beyond these aspects of the social structure of the school, other criteria have to be met by a school in order to be able to produce works of scientific eminence. A school needs an institutional affiliation; the higher in the rankings of academia, the better, because of the social and cultural capital related to such an affiliation. Further, the school needs some form of regular publication, usually one or two journals or book series. Also, a manifesto is required, a "document in the nature of a professional proclamation of [the schools] basic mode of perceiving and relating to the world" (Tiryakian, 1979: p. 223).

Tiryakian also offers some thoughts on the trajectories of schools, which roughly resemble Nicholas Mullins' characterization of developmental stages of what he calls 'theory groups' (Mullins, 1973). The distinctiveness of the system of thought developed by the school attracts both attention and new members. This leads to an increased visibility of the school within academia. Its ideas become popularized and are melted into the standard body of knowledge of the discipline. Also, the "charisma of the school becomes 'routinized'; […] The more the school and its achievements become integrated into the discipline, the more depersonalized becomes its paradigm" (Tiryakian, 1979: p. 218). This depersonalization, on the one hand, leads to a higher freedom in using and transforming the ideas. On the other hand, their specific sociocultural origins slowly fall into oblivion, as do those presuppositions that did not find their way into the written products of the school – basic ontological, metaphysical, existential, and perhaps ideological groundings of a paradigm. "Over time, and with an increased and perforce more heterogeneous membership, the presuppositions of the school become blunted, diluted, trivialized, or compromised" (Tiryakian, 1979: p. 218).

Apart from identifying schools and roles within them, historical analyses of institutional schools usually address one of two more general problems. One relates to the consequences of the existence of such schools for the development of knowledge. This issue is treated in more detail in the next section. The other more general set of problems is concerned with the importance of local practices in research. The separation of these two problems is mainly of analytical value. Of course, these two problems are interrelated, because they both converge on the importance of tacit forms of knowledge (Polanyi, 2005), of knowledge that does not travel easily on written documents but is acquired through model-learning or hands-on experience.

Historical Relevance

Tiryakian conceives of schools as being oriented toward the discipline at large. The mission of its members is to spread the doctrines of the founder-leader. Granted this (which is disputed; see next section), schools can be identified as important units in the development of SBS, firstly because they are key agents in the process of academic institutionalization of a new discipline. Secondly, they play a paramount role in the

cognitive development of a discipline. Because "[t]he articulation and demonstration of the efficacy of a new methodology are much more a communal affair than that of a single individual" (Tiryakian, 1979: p. 211), schools are the places where innovative paradigms are crafted. The growth of sociology "to a large measure represents, or is a function of, periodic infusions brought about by a small number of major 'schools'" (Tiryakian, 1979: p. 211).

While the justification part of the above explanation – that new paradigms usually are the product of a collective – is certainly correct, the assertion that a school is the most important social form capable of uniting scholars to collaborate on the articulation and presentation of a system of thought is dubious. All the more interesting is the striking similarity of Tiryakian's argument to the coeval discourse in Marxist philosophy of science. Referring to the notion of a scientific and technological revolution established by Radovan Richta in the 1960s, the editors of a book on scientific schools that emerged from a series of colloquia among researchers from the Academies of Science in Moscow and East Berlin wrote in the introduction that "the task to investigate the collective creativity in science and research and lead it to its highest efficiency gains crucial importance for the acceleration of the scientific and technological progress" (Mikulinskij et al., 1977b: p. 7, vol. I; see also Mikulinskij et al., 1977a). To them, scientific schools are paramount for scientific progress, because they are "a type of organization that realizes the dialectical unity of individual and collective epistemic progress" (Mikulinskij et al., 1977b: p. 9, vol. I). While it will not be possible to create schools by *fiat*, "the comprehensive, but partly widely scattered material on the past and present of scientific schools must be collected and analyzed to generate recommendations for the design of creative work under the conditions of socialized science in the developed socialist society" (Mikulinskij et al., 1977b: p. 9, vol. I).

It has been noted that the debate on scientific schools has been more widespread in formerly socialist countries (Stichweh, 1999: p. 23f.). Philosophers and sociologists of science in East Europe and Russia were indeed cognizant of the works of English-speaking scholars, while the opposite has not always been true. The criteria for defining a school developed by Eastern scholars, however, do not differ much from Tiryakian's; for instance, Eduard Michajlovič Mirskij defines the following characteristics of a school (in the natural sciences): (1) it is a coalition of researchers with a high-profile leader which locates itself within the wider scientific community; (2) it exists as an autonomous entity which is in opposition to the wider community both with regards to the content and procedure of scientific work and to scientific standards and norms; (3) the research program proposed by the school differs from those proposed elsewhere; (4) its existence is caused by a set of factors that include objective factors, like the research program, as well as subjective factors, like the personality of its key members; (5) the research program must be productive, i.e., it must be capable of being developed; (6) the scientific authority of the leader of the school must be acknowledged by the academic environment; (7) both composition and growth of a school depend on the organizational capabilities of its leader; and (8) the value of a school is not only to be seen in its research program. The existence of a school also contributes to the maintenance of a continuous "interest in the explication and critical discussion of problems of theory and methodology within a given research area […] [T]he scientific school is virtually the only type of environment which *forces each member* to consider critically the tenets common in his science and to see them as mere *conventional assumptions of a specific group of scientists*" (Mirskij, 1977: p. 188f.). Despite the apparent consensus about the core features of schools as institutions, there is a richness of interesting and nuanced differences in their treatment of the notion of school by Marxist authors (e.g., Gasilov, 1977; Laitko, 1977). Furthermore, all the cited authors agree that the importance of the formation and existence of schools with regard to the growth of knowledge cannot be underestimated, be it in the SBS or in other areas of scientific endeavor.

Discussion

The supposed existence of schools as institutions in academic life has often led to severe criticisms. Informed in part by Robert K. Merton's (1996) treatment of the ethos of science, and in striking contrast to the apparent consensus on the positive functions of schools for the development of science described above, scholars have argued that schools are closed and introverted systems characterized by "the uncritical acceptance by a group of disciples of a leader's idea system" (Krantz, 1972: p. 86). They emphasize a sectarian meaning of the notion of school, arguing that schools reject external influence and validation of their work. The creation of new publication outlets by the school is seen as a measure to "bypass the criticism of referees from other areas" (Crane, 1972: p. 87). The existence of schools invariably leads to either a field-internal segregation or a prolonged confrontation; especially in the latter case, these authors expect the growth of the field to be inhibited.

The viability of an institutional conceptualization of schools within the history of SBS has also confronted criticism, and its use has declined in the past decades. Most criticism focused on the supposed stability within schools, both with regard to the internal hierarchization and role distribution, but also with regard to the system of thought and the commitment of the individual members to it. A school is more fragile an institution and individuals more ambivalent toward their own membership in them than these concepts suggest. Also, it is not easy to demarcate a school as historical entity. A rather recent, highly sophisticated approach has been developed by Andrew Abbott (1999), who argued that the first Chicago school (A.W. Small, R.E. Park, E.W. Burgess, W.I. Thomas, L. Wirth, etc.; cf Bulmer, 1984) in sociology can be treated as a historical entity for its social structural consequences. These initiated a complex process of mutual reinforcement, which did not only intensify the structural consequences, but out of which also emerged the Chicago school as a cultural object. "The Chicago School was not a fully formed cultural object until after it had virtually completed its life as a social structure." The cultural object, thus, is to a high degree a retrospective creation of the second Chicago school period after World War II (E.C. Hughes, H. Blumer, W.L. Warner, etc.; cf Fine, 1995).

Methodological Considerations

The specificities of the two concepts of school discussed above come into view best if contrasted with neighboring concepts with a focus on the respective implications for the design of a study in the history of SBS. In the case of typological schools, the most obvious are analyses of textbooks (Platt, 2008). Recently, another research design has been suggested by Green et al. (2013). Their approach has been to quantify the level of verbal similarity between pairs of articles published in a predefined period in a selected journal. Such methodologically sophisticated analysis has become less difficult in the course of the digitalization of scientific knowledge.

Comparable studies of communication processes in science have also informed many of those concepts that can be seen as neighboring the institutional concept of school, such as 'invisible colleges' and 'theory groups'. Invisible colleges are communication networks that link the leaders of local research groups and usually comprise about 100 scientists (Price, 1963). These leaders "communicate with each other and transmit information informally across the whole field. This enables them to monitor the rapidly changing research 'front' and to keep up with new findings during a period of rapid growth" (Crane, 1972: p. 35). The concept of theory groups considers a broader variety of social relationships between individual scientists and includes a developmental perspective on the institutionalization processes of a theory group (Mullins, 1973). Mullins's conceptualization offers a fruitful empirical framework that, apart from a quantitative analysis of communication patterns, also investigates many features of the above characterization of schools (basic manifesto, intellectual leader, organizational leader, etc.); however, as his own analyses show, this framework can also be too ambitious.

Analyses of schools as institutions usually rely on historical and archival work in search for sources that document the internal organization of the school. The objective of such research is to gain insights into the cultural life of the school, and to show how this is reflected in the works of the members. Citation analyses and the like are only of secondary relevance. This also holds true for the concept of academic tribes (Becher and Trowler, 2001). By academic tribes, the authors understand the distinctive cultures within academic communities. The emphasis is on the relation of these cultures to the academic ideas they propagate – the territories, in Becher and Trowler's words. The relationship between the two "involves a mutually dependent interplay of, on the one hand, the structural force of the epistemological character of disciplines that conditions culture and, on the other, the agentic capacity of individuals and groups for autonomous action, including interpretative acts" (Becher and Trowler, 2001: p. 23f.). In both cases, thus, the analysis is more on the cultural aspects of academic life and its relations to the prevailing ideas within these social entities. The methodologies used in this line of work are predominantly of an interpretative kind.

Conclusion

A brief outlook on the future of the concepts here described might be appropriate. In general, there is reason to assume that the notion of schools of thought, due to their didactic function and their role in theoretical debate, will remain in use, though this does not necessarily apply for the term itself. The trajectory of the institutional concept of schools is dubious. A variety of factors that characterize contemporary academic life appear to counteract the establishment of schools: the increasing amount of temporary contracts makes it hard to maintain a stable core of collaborators; the standardization of academic education and the internationalization of the academic labor market transform the decision to commit to an idiosyncratic (though perhaps highly innovative) paradigm into a highly critical career decision, because of the potential lack of connectability of one's own work to the 'mainstream'; the mere population size of SBS disciplines has increased dramatically during the last century, so that the attention space available for alternative paradigms decreases; and finally, the internationalization of the SBS and the gradual erosion of national academic spaces homogenize the academic landscape, so that if institutional schools will emerge in the future, they will probably do so in the metropolitan centers of this homogenized, global landscape.

Schools, Micropolitics of

Herbert Altrichter and Robert Moosbrugger, Johannes Kepler University, Linz, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

'Micropolitics' is a specific perspective in organization theory. It focuses on activities within organizations to acquire, develop, and use power and other resources. This article explores the uses and usefulness of this concept in educational research. It starts with outlining the micropolitical view on educational organizations, then gives some examples of representative micropolitical research in order to illustrate typical topics and research strategies. The article concludes with discussion on criticisms of micropolitics and indicating areas for future development.

'Micropolitics' is a specific perspective in organization theory. It focuses on "those activities taken within organizations to acquire, develop, and use power and other resources to obtain one's preferred outcomes in a situation in which there is uncertainty or dissent" (Pfeffer, 1981: p. 7) because it considers them as most important for the constitution and the workings of organizations.

This article explores the uses and usefulness of this concept in educational research. It starts with outlining the micropolitical view on educational organizations. Then, it gives some examples of representative micropolitical research in order to illustrate typical topics and research strategies. Finally, it discusses criticisms of micropolitics and indicates areas for future development.

The Concept of Micropolitics

Main Elements

Traditional organizational theories of different origins seem to converge in describing organizations as goal-oriented and rationally planned, characterized by stable objective structures, a high degree of integration and a common purpose of its members. Conflicts between the members of an organization are considered costly and irrational 'pathologies' to be eradicated as soon as possible. This view on organizations which has also been used for studying educational establishments suggests "that it is possible within schools to arrive at a time and place where politics and conflict are not present" (Flessa, 2009: p. 340).

However, conflicts are endemic in organizational life (Ball, 1987), they are a "naturally occurring phenomenon" (Achinstein, 2002: p. 422). Different stakeholders pursue their own interests which are not necessarily identical with the formulated goals. Coalitions are formed, meetings are boycotted, and formal structures are ignored. As such phenomena frequently occur in organizations, it is not helpful to exclude them from organizational theorizing: models are needed which can cope with this "dark side of organizational life" (Hoyle, 1982: p. 87) and take account of the complexities "in managing a diversity of beliefs and practice while maintaining strong communities" (Achinstein, 2002: p. 422). Such models also offer the chance to examine and learn from conflict (see Flessa, 2009: p. 331; Achinstein, 2002: p. 422). They challenge traditional rational theories of organizations by highlighting the difference between 'policy rhetoric' and reality (Björk and Blase, 2009: p. 198); what micropolitics is interested in is "the study of how things *really* work, not how an organizational chart or a principal's action plan would like them to work" (Flessa, 2009: p. 331).

The micropolitical perspective was originally developed in the realm of profit organizations (see e.g., Bacharach and Lawler, 1980; Pfeffer, 1981). In a 1982 seminal paper, Eric Hoyle put forward arguments for exploring the concept also for education. In 1987, Stephen Ball published the book *The Micro-Politics of the School* in which he used empirical material to push the development of the concept. In its wake the term 'micropolitics' appeared more frequently in various research papers (see e.g., Blase, 1991 for a representative collection). What are the main elements of a micropolitical view of schools:

1. The micropolitical perspective is based on a specific *view of organizations*. They are seen as characterized by diverse goals, by interaction and relationships rather than structures, by diffuse borders and unclear areas of influence rather than clear-cut conditions of superordination and delegation, by continuous, unsystematic, reactive change rather than by longer phases of stable performance and limited projects of development. The main focus of micropolitical approaches is not the organization as it aspires to be in mission statements and organizational charts, but the organization-in-action and, in particular, the "space between structures" (Hoyle, 1982: p. 88), which produces enough ambiguity to allow political activities to flourish.
2. A micropolitical approach is based on a specific *image of actors*. Members of organizations are characterized by differing interests, goals, status, power, and authority and are "pursuing their own interests, resulting in fights over real and symbolic resources" (Kelchtermans and Ballet, 2002a: p. 107). Actors may do this as individuals; they may coalesce in loosely associated interest sets, or use subdivisions of the organization (e.g., departments, professionals vs administration) as power bases. In an organization everyone influences everyone, regardless of job, title, or formal position (Brosky, 2011: p. 8). In order to protect or enhance their organizational room for maneuver, actors aim to retain or obtain control of resources, such as the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92070-1

following (see Kelchtermans and Vandenberghe, 1996: p. 7; Ball, 1987: p. 16):

a. *Material resources*: such as time, funds, teaching materials, infrastructure, and time tabling.
b. *Organizational resources:* such as procedures, roles and positions which enable and legitimate specific actions and decisions. They define 'prohibited territories' and relationships of subordination or autonomy. Thereby, they have their bearing on the actors' chances to obtain other resources (e.g., through career and participation).
c. *Normative or ideological resources*: such as values, philosophical commitments, and educational preferences. A particularly important ideological resource is the 'definition of the organization' which indicates what is legitimate and important in the organizational arena.
d. *Informational resources*: The members of an organization are interested in obtaining organizationally relevant information and to have their expertise, knowledge, and experience acknowledged.
e. *Social resources*: Affiliation to, support from, and reputation with influential groups within and outside the school are assets which may be mobilized for one's organizational standing.
f. *Personal resources:* also personal characteristics – such as being respected as a person and being grounded in an unchallenged identity as a teacher – are resources in organizational interactions.

3. A micropolitical perspective pays special attention to *interaction processes in organizations*. Schools are arenas of interaction and struggle, and it is interaction which ultimately produces their specific shape. Activities and decisions of actors in these arenas may be understood as contributing to some formal organizational goals; however, at the same time and with the same activities actors are using their influence and power, formal and informal, in order to foster their own interests and goals (see Malen and Cochran, 2008: p. 149; Blase and Blase, 2002: p. 9). Although schools are reflecting the society they are located within (see Caffyn, 2007: p. 345) and are bound to and influenced by law and guidelines, their organizational structures and processes are critically shaped by power struggles within them (see Busher, 2001: p. 80; Brosky, 2011: p. 2). Micropolitics influences all types of decision making, behavior, processes, and structures. The shape of the organization, its norms and values, and its strategies for goal attainment, are the result of ongoing micropolitical interactions within and among individuals and groups related to the organization (see Blase, 2005: p. 265). This has the following implications:
   a. Organizational interaction is seen as *conflictual and competitive*, "as a continuing struggle for control, power and influence" (Eilertsen et al., 2008: p. 300). "Confronted by competition for scarce resources and with ideologies, interests and personalities at variance, bargaining becomes crucial" (Gronn, 1986: p. 45). The relationship between control and conflict (or domination and resistance) is conceived "as the fundamental and contradictory base of organizational life" (Ball, 1994: p. 3822).
   b. Organizational interaction is *power-impregnated*. It draws on the resources mentioned above for influencing the workings of an organization. However, these resources have to be mobilized in interaction in order to become 'power.'
   c. Power *is in need of relationship*. In order to satisfy his or her interests an actor needs some interaction from other actors. Power builds on dependency which makes the relationship reciprocal, but, as a rule, asymmetric.
   d. Actors use a multitude of *strategies and tactics* to interactively mobilize their resources and to prevent others from doing so, such as setting the agenda of meetings, boycotting and escalating, avoiding visibility, confronting openly or complying, and carefully orchestrating scenes behind closed doors or in public arenas.
   e. *Micropolitical literacy* is an important competence of organizational actors. Actors who are well aware of micropolitics are in the position to cope with conflicts and profit from them (see Achinstein, 2002: p. 450). In order "to be effective in political environments, individuals need to possess *political skill*. Political skill refers to the exercise of influence through persuasion, manipulation, and negotiation" (Brosky, 2011: p. 3). Actors who are micropolitically literate are able to read the power aspect of organizational interaction and to navigate through roles, power, interests, and norms within an organization (Curry et al., 2008: p. 662).
   f. Power is employed *from both ends of the organizational hierarchy*. There are advantages of position, however, "micropolitical skills may be well distributed throughout the organization and position is not always an accurate indicator of influence" (Ball, 1994: p. 3824). For example, Brosky (2011: p. 4) identified six influence tactics used by subordinates: (1) *ingratiation*: for example, getting another actor in good mood; (2) *exchange*: using promises, rewards, benefits, and so on; (3) *rationality*: relying on logical arguments and evidence; (4) *assertiveness*: requesting in a forceful manner; (5) *upward appeal*: appealing to higher instances; and (6) *coalitions*: seeking the aid of others.
7. *Organizational change is non-teleological, pervasive, and value laden* since it advances the position of certain groups at the expense of the relative status of others (see Ball, 1987: p. 32). Schools are not organizations easily changed; a 'quick-fix orientation' in innovation will not be appropriate to their cultural complexities (see Corbett et al., 1987: p. 57).

Micropolitics certainly cultivates an interest in the conflict side of organizational interaction. Conflict offers special opportunities for both theoretical understanding and practical development of organizations. However, conflict also "generates opportunities to strengthen communities, for in the conflict lies an occasion to examine differences of beliefs, solicit alternative voices, bridge across differences to find common ground, and seek opportunities for change and growth" (Achinstein, 2002: p. 449). In this view, conflicts do not necessarily have a negative impact, they also offer an opportunity to learn and grow. Nevertheless, 'embracing conflicts' may be less appealing to those who have to live with them. Frustration about repeated conflicts and unsolved problems may result in stress, burnout and, as

a consequence, in high teacher turnovers (see Achinstein, 2002: p. 449).

Conflict is endemic to organizations, although, it need not be dominant in all instances. Political systems do have conflicting and cooperative elements. Collaboration, coalition, routine, unspoken nonaggression pacts, outspoken negotiations, political alliances, and obligations may establish comparatively smooth time spans in organizational life (see Kelchtermans and Ballet, 2002a: p. 107; Blase, 2005: p. 264). However, also these are considered to be power-impregnated, representing a more or less fragile balance of power.

Research in the Micropolitics of Education

Methods and Strategies

Micropolitical processes are a constant and normal part of organizational life and they contribute to the organizational shape and to the performance of a school. Studying micropolitics may help to understand why schools operate the way they do and to explain organizational outcomes which do not seem 'rational' at first sight. It may help identifying relevant actors who are not highlighted by the official organizational charts and ways of operating and problem solving which have not been foreseen by the respective organizational guidelines.

However, if part of the micropolitical activities which are interesting for the researcher take place in privacy, if these processes are often overlain by routine activities (see Ball, 1994: p. 3822), and if experienced actors regularly use strategies such as covering up actions and deceiving about real intentions, then researching the micropolitics of schools will have to cope with some methodological problems. To come to grips with their object of study, micropolitical studies focus on critical incidents, persons, and phases that disrupt routine (e.g., the appointment of a new principal, or the introduction of new tasks or programs), instances of structural reorganization (e.g., a school merger), and so on. Micropolitical studies pay special attention to the processes of (re-)distribution of resources, rewards, and benefits (see Ball, 1994: p. 3823) or analyze instances of organizational conflict to find out how new organizational order has been established. These strategies provide a quicker access to indicative processes, but are certainly in danger of inducing an overestimation of the proportion of conflict in organizations. Micropolitical studies try to enhance their credibility through triangulation of methods, collection of multiple perspectives, long-term engagement in the field, critical discourse in a team of researchers, and feedback from participants and external researchers. Although there have been some attempts to tackle organizational micropolitics with quantitative means (see e.g., Blickle, 1995), most studies are based on qualitative methods. There have been interview and observation studies, however, the typical strategy is a case study approach mainly based on interviews, field notes from participant or non-participant observation, transcripts of meetings, analyses of documents, and cross-case comparison of different sites.

A good example of such a case study is Sparkes' (1990) 3-year study of a newly appointed departmental head's attempts at innovation: The head seeks to orientate Physical Education teaching toward a child-centered approach emphasizing mixed-ability grouping and individual self-paced activities which runs counter to the then prevalent 'sporting ideology.' In the beginning, the new head believes in rational change and democratic participation. He tries to make other department members understand his own particular teaching approach before introducing changes to the curriculum. However, not all staff can be convinced through dialogue.

In his management position the departmental head can control the agenda of department meetings, time and procedure of arriving at decisions, and so on. He secures the agreement of crucial staff members before the meetings and networks with other influential persons outside his department. His proposals for innovation are nevertheless met with resistance by some staff. However, this resistance cannot prevent the structural changes being introduced. On the other hand, these structural changes cannot guarantee teachers' conformity to the head's educational goals within the confines of individual classrooms. Thus, he goes on to consolidate his domination of the department by careful selection of new staff and exclusion of the unwilling.

Although being successful in that his proposals for curriculum change were implemented within one year, the departmental head ended up in a situation that was characterized by conflict and uncertainty and, thus, in many respects, counteracted his own aspirations of democratic leadership. Sparkes suggests that his findings have some bearing beyond the specific case. He warns that the "ideology of school-centered innovation … fails to acknowledge the presence and importance of conflict and struggle both within, and between, departments. … the commonly held view of teacher participation in the innovative process as 'good' in itself is highly questionable. The findings presented indicate that qualitative differences exist in the forms of participation available to those involved and that, to a large extent, these are intimately linked to the differential access that individuals have to a range of power resources" (Sparkes, 1990: p. 177).

Research Topics

Potential topics are manifold. Björk and Blase (2009), for instance, analyzed how strategic alliances by district middle managers hampered efforts of decentralization, Kelchtermans and Ballet (2002a) studied beginning teachers efforts in coping with the 'real-life requirements' of their profession, and Chen (2003) investigated strategies of candidates in schoolhead election at a primary school in Taiwan. The most typical topics of micropolitical studies include:

Processes of Change

When organizational 'routine games' are disrupted, for example, through educational, curricular, or organizational innovations, through the recruitment of new principals or teachers, through the introduction of quality assurance systems, then intensified processes of micropolitical relevance are to be expected. Some studies investigate how externally mandated reform is dealt with in schools: When Ball and Bowe (1991: p. 23) studied the impact of the 1988 British Educational Reform Act, they found that "the implementation of externally initiated changes is mediated by the established culture and history of the institution, and that such changes,

their acceptance, and their implementation become sites as well as the stake of internal dispute." The reform puts some possible alternative definitions about the meaning and the workings of schools on the agenda which have to be 'processed' in the local environments through disputes over topics such as "serving a community versus marketing a product" or "priority to managerial or professional views of schooling."

Leadership

Traditionally, educational ethnography had a strong classroom orientation. Micropolitics may be understood as a move to apply ethnographic methods to study the interaction of the members of the school outside the classroom. Although parents,' pupils,' and ancillary staff's voices are included in some studies, most research focuses on the interaction of teachers. Since steering and regulation of school work are at the heart of the micropolitical approach, it is no wonder that issues of leadership have been frequently investigated (see e.g., Ball, 1987: p. 80). Focusing on leadership does not mean personalizing organizational affairs, since leadership is seen as a political process, as "one of the best policy levers to pull to achieve desirable ends" (Flessa, 2009: p. 337).

School leaders play a central role in shaping a school. They significantly affect the school culture, define basic rules, and determine topics and agendas as well as responsibilities and tasks of other members (see Ehrich and Cranston, 2004: p. 2). By having the power to reward or punish they show subordinates the potential costs of actions (see Malen and Cochran, 2008: p. 161). Evidence shows that the micropolitical orientation of teachers varies according to those of their principals. 'Open principals' provoke an open and diplomatic stance in teachers while a closed or manipulative principal encourages protective actions like avoidance and ingratiation (see Blase and Blase, 2002: p. 15).

Holders of senior positions must acquire micropolitical skills for their career advancement and for managing organizational control (see Ball, 1994: p. 3824). "(…) the skill school leaders need is not the perfect strategy to engage in the impossible struggle to eliminate micropolitics but instead the skill of inquiry to look for it in every instance, to examine who gains and who loses under important school decisions, and to develop a better understanding of the concerns that motivate people to join together in support or opposition" (Flessa, 2009: p. 346). Skilled headpersons can read conflicts as sources of information about what matters most to various school stakeholders.

Managing Relationships within the Organization and with Stakeholders

Under organizational conditions the welfare of children is bound to the well-being of the adults who work with them (Nias, 2005: p. 228). Analyzing the micropolitics of schools often means analyzing adults' behavior at the workplace. Colleagues are, not only for beginning teachers, an important source for backup, assistance, new ideas, and emotional support, but also may be potential partners for discussion, for sharing knowledge, for advice, and for consolation. Overall, they may be of great help to cope with the demands of being a teacher (see Nias, 2005: p. 204), but they also may be a source of constant pressure, distress, or uncertainty. Working conditions and relationships in and around school are on the one hand significantly influencing school culture, and on the other hand influenced by school culture itself. They have an impact on how different demands and issues are dealt with, on the overall satisfaction of staff members and other stakeholders, and on the output of the organization.

Socialization and Professional Development of Teachers

The politically impregnated organizational climate in schools is the context in which individual teachers develop their professional identity (Kelchtermans and Vandenberghe, 1996). Teachers do not only have to deal with issues at the classroom level, but are also members of an organization and confronted with 'the micropolitical reality' of the organization (see Kelchtermans and Ballet, 2002a: p. 105). Thus, micropolitical literacy would be important for beginning teachers who are to develop their professional identity in a political arena. However, training programs for teachers usually fail to provide sufficient preparation for this aspect of work life; the same holds true for programs of leadership development, although in the meantime to a lesser degree.

During the first years of their career, teachers concentrate on acquiring knowledge and competencies with respect to academic and control aspects of classroom instruction. Later on they build up a 'diplomatic political perspective,' because they feel under 'constant scrutiny' by pupils, parents, fellow teachers, and administrators (see Blase, 1991: p. 189; Kelchtermans and Vandenberghe, 1996). A pervasive feeling of 'vulnerability' induces many teachers to develop a range of protective strategies such as low-risk grading, documentation of assessment and instruction, and avoidance of risky topics and extracurricular activities (see Blase, 1991: p. 193). Thus, it is no wonder that some authors claim that the acquisition of political competence is fundamental to teachers' career satisfaction (see Ball, 1994: p. 3824). "Explicitly and implicitly, most micropolitical studies of teaching have demonstrated that teachers routinely use power strategies to influence and to protect themselves from others (particularly principals, parents, and students) and that they develop cognitive and affective responses consistent with a micropolitical perspective" (Blase and Blase, 2002: p. 14).

Understanding Schools as Organizations

Since micropolitics is an approach to organization theory, all these studies aim to contribute to our understanding of schools as organizations. Schools as organizations are placed in an environment of complex relationships where they are confronted with diverse requirements from parties within and outside its boundaries (Caffyn, 2007). Many studies prove the intensity of power-impregnated activity in schools and analyze typical causes and process forms. It has been argued that political control strategies are a characteristic part of school life "precisely because the professional norms of teacher autonomy limit the use of the effectiveness of more overt forms of control" (Ball, 1994: p. 3824).

In Iannaconne's (1991: p. 468) view, the unique contribution a micropolitical approach can offer lies in exploiting the metaphor of 'society' for schools: A typical school is organized like a 'caste society' since a majority of its

members are "subject to its laws without the right to share in making them" (Iannaconne, 1991: p. 469). From the characteristics of a 'caste society' some hypotheses about schools may be derived, for example: (1) Such societies are characterized by great tensions between the castes and a fragile balance of power. (2) They tend to conceal the internal differences of a caste from others. Consequently, critical self-examination of castes and open debate over policy issues is difficult. (3) They tend to avoid fundamental conflicts and to displace them into petty value conflicts. "In schools, as in small rural towns, the etiquette of gossip characterizes teacher talk. Faculty meetings wrangle over trivial matters, avoiding philosophic and ethical issues like the plague" (Iannaconne, 1991: p. 469).

Achinstein (2002) contrasts two schools and their differences in dealing with conflict over underscoring pupils. One school is, in accordance with Iannaconne's analysis, avoiding conflict at all cost. Head and staff employ strategies in order to avoid conflict or immediately restore consensus, for example, blaming students, avoiding criticism of teaching practices, sarcasm, and choosing the 'right staff.' In contrast, the other school – a 'conflict embracing community' – has established a culture where conflict is seen as something to learn from. Norms, values, and practices are constantly contested and double loop learning takes place.

Conclusion, Criticism, and Areas for Future Development

The first wave of research and conceptual work in micropolitics in the beginning of the 1990s has not only triggered some criticism which will be discussed in order to identify possible limitations, but also areas for future development:

1. Many authors of the micropolitical approach revel in examples of illegitimate strategies: secrecy, deception, and crime add much to the thrill of micropolitical studies. Some critics argue that talking about the pervasiveness of 'illegitimate power' *produces itself a 'micropoliticization' of practice and will undermine confidence in organizations*. This claim implies that a second meaning of 'micropolitics' is introduced: It does not (only) refer to an *approach in organization theory* (which analyses both legitimate and illegitimate interactions and their effects for the structuration of an organization), but refers to those *specific activities and attitudes* in organizations which are markedly based on power politics with illegitimate means. This conceptual move, however, produces problems: How should it be possible to draw the line between 'good' and 'bad organizational politics' since it were precisely situations characterized by diverse goals and contested expertise which made a concept like 'micropolitics' necessary? (see Kelchtermans, 2005: p. 1001)
2. Although the proponents of micropolitics authors are right to criticize a presupposition of organizational consensus, it is unsatisfactory to interpret any consensus as a form of domination (see Ball, 1987: p. 278; but also Ball, 1994: p. 3822). Many early studies did not include cooperative or consensual interactions (see Blase, 1991: p. 9). It is necessary to develop conceptual devices to account for relationships of co-agency which neither dissolve any cooperation into subtle forms of domination nor gloss over the traces of power which are at the core of collaboration and support (see Altrichter and Salzgeber, 2000: p. 104).
3. In focusing on strategic aspects of action, micropolitical approaches are again in danger of *overemphasizing the 'rationality' of organizational action*. To understand the workings of organizations it may be necessary to consider actions which are mainly influenced by emotions and affect, which have not been carefully planned according to some interests, as well as unintended consequences of otherwise motivated actions. Kelchtermans and Ballet (2002b: p. 765) distinguish three aspects of micropolitical literacy: (1) knowledge – seeing, understanding, and interpreting micropolitics in a particular situation; (2) instrumental aspect –the 'repertoire' of micropolitical strategies; and (3) experiential aspect – how confrontation with micropolitical reality is experienced. In particular, when highly valued issues – such as the self-understanding as professionals and working conditions – are at stake, intense emotions are triggered (see Kelchtermans, 2005: p. 1004).
4. Although being right to put the spotlight on the potential instability of organizational processes, early micropolitical studies had some difficulty in conceptualizing *the relative stability and durability of organizations, which we can observe day in, day out in many organizations*. For this purpose, it will be necessary to bring agency and structure in a balanced conceptual relationship: micropolitics will not deal with "relationships rather than structures" (Ball, 1994: p. 3822), but put precisely with the interplay between interaction and structure.
5. The *understanding of politics displayed in many early micropolitical studies was quite unsatisfactory, not to say unpolitical*. Politics was often seen as the opposite of truth and reason; it was associated with treason, conspiracy, and accumulation of influence as if fair and democratic ways of negotiation in organizations were inconceivable.

   Many of these problems may be overcome by reference to Giddens' (1992) theory of structuration, Crozier and Friedberg's (1993) concept of organizational games, and Ortmann et al. (1990) studies of power in organizational innovation. On this conceptual basis, organizational structure may be seen as an outcome of and resource for social actions which enables and restricts actions, but never fully determines them. Organizations are webs woven from concrete interactions of (self-)interested actors. They acquire some spatial–temporal extension through the actors' use and reproduction of 'games.' The 'game' is the point of conceptual intersection in which the analytically divided elements of agency and structure, of individual and organization meet. The game works as an "indirect integration mechanism which relates the diverging and/or contradictory action of relatively autonomous actors" (Crozier and Friedberg, 1993: p. 4). In order to take action and to pursue their own interests members of organizations must at least partly use structural resources of the organization, that is, they are forced to play within the organizational rules, and thereby, they reproduce these rules. The functioning of an organization may be explained as "result of a series of games articulated

among themselves, whose formal and informal rules indirectly integrate the organization members' contradictory power strategies" (Ortmann et al., 1990: p. 56). The interlocked character of the games and the high amount of routine elements in social practices are major reasons for the relative stability of organizations (see Altrichter and Salzgeber, 2000: p. 106).

6. It was also criticized that in some micropolitical studies *the external relationships of the organization were dissolved into the interactions between individual actors*. On the other hand it must be said that many studies took care to account for the societal embedding of organizational interactions (see e.g., Ball and Bowe, 1991). In the meantime there is general agreement that this must be a feature of sound micropolitical studies (see Blase, 1991: p. 237).

This is even more important since many national schools' systems have recently faced and are still facing massive changes in their governance structure. New policies, such as standards, accountability, autonomy, and access policies, have to be implemented at district and school levels, necessarily involving micropolitical struggles over the new distribution of rights and resources (Altrichter et al., 2014) and producing ambiguous situations: Schools are required to act in the interest of its students and according to the professional norms of its staff while at the same time to "pursue broader social and economic imperatives" (Johnson, 2004: p. 268). New policies are also providing new levers for external influence on schools, for example, accountability policies contain the "potential to produce information that attentive publics … might use to press for school reforms that they view as key" (Malen and Cochran, 2008: p. 152).

Theoretically, these developments in the field call for linking analyses on macro- and micro-political level. The 'New Model of Micropolitics' by Smeed et al. (2009) begins with recognizing the impact of the macropolitical context – for example, heightened accountability requirements, testing, and pressure from the wider community – on the micropolitics at school level. Some researchers who have contributed to the literature on micropolitics have recently turned to study the *governance of school systems* (e.g., Ball, 2007). Governance studies aim to analyze how systemic coordination is achieved by the transactions of various social actors in a multilevel system (de Boer et al., 2007; Altrichter, 2010). It is particularly important to understand how new policies which have been developed on a particular system level are perceived on another level (e.g., on school level) and translated into agency and structures adequate to the norms and work traditions prevalent on this level. Fend (2006: p. 69) has captured these processes of translation and transformation by the concept of 'recontextualization' and we will not go wrong by assuming that these processes are 'micropolitical' in that they may be conceived as negotiation of interested actors in a power-impregnated field.

Abstract

Joseph A. Schumpeter (1883–1950) is generally considered one of the major economists of the twentieth century. He was born in the Austro-Hungarian Empire but emigrated to the United States in the 1930s where he worked as a professor of Economics at Harvard University. Schumpeter's most important contribution is to the theory of entrepreneurship, especially as developed in *The Theory of Economic Development* (1912; trans. 1934). According to Schumpeter's well-known definition, entrepreneurship means "the carrying out of new combinations." His work *Capitalism, Socialism and Democracy* (1942) is probably his best-known work and is regarded as a classic not only in economics but also in political science. Of special interest in this work is Schumpeter's definition of democracy as the election by the people of a new elite.

Joseph A. Schumpeter (1883–1950) is generally considered one of the major economists of the twentieth century. His main effort was to develop a theory of economic change that could complement Walras' theory of general equilibrium. Schumpeter centered his theory of economic change on the entrepreneur, and in *Theorie der wirtschaftlichen Entwicklung* (1912; tr. 1934) he defined entrepreneurship as "the carrying out of new combinations." The initial innovation, according to Schumpeter, attracted other entrepreneurs and eventually set off a business cycle. Schumpeter's best known work is *Capitalism, Socialism and Democracy* (1942), which is regarded as a classic not only in economics but also in political science. Several of Schumpeter's analyses in this work are still controversial in nature, such as his suggestion that monopolies can be healthy for the economy and that modern capitalism is digging its own grave and preparing the road for socialism. The most celebrated contribution of this work, however, is to be found in Schumpeter's discussion of democracy, more precisely in his critique of the traditional way of defining democracy as an attempt to realize the will of the people and in his own preference for a definition of democracy as competition among political leaders for the votes of the citizens.

Joseph A. Schumpeter is one of the best known and most flamboyant economists of the twentieth century. His main accomplishments are to have introduced the entrepreneur into economic theory through *Theorie der wirtschaftlichen Entwicklung* (1912) and to have produced a magnificent history of economic thought, *History of Economic Analysis* (posthumously published in 1954a). Schumpeter's interests were wide ranging, and his writings also include contributions to sociology and political science. His analysis of democracy, which can be found in his most popular work, *Capitalism, Socialism and Democracy* (1942), is generally regarded as an important addition to the theory of democracy.

Early Life and Career

Joseph Alois Schumpeter was born on 8 February 1883, in the small town of Triesch in the Austro-Hungarian Empire (today Trest in Slovakia). His father was a cloth manufacturer and belonged to a family that had been prominent in the town for many generations, and his mother, who was the daughter of a medical doctor, came from a nearby village. Schumpeter's father died when he was 4 years old, an event that was to have great consequences for the future course of his life. Sometime later, his mother moved to Graz and then to Vienna, where she got married to a retired officer from a well-known, aristocratic family, Sigismund von Kéler. Schumpeter was consequently born into a small-town bourgeois family but raised in an aristocratic one, and his personality and his work were to contain a curious mixture of values from both of these worlds.

After having graduated in 1901 from the preparatory school for the children of the elite in the Empire, Theresianum, Schumpeter enrolled at the University of Vienna. His goal from the very start was to become an economist. Around the turn of the century, the University of Vienna had one of the best educations in economics in the world, thanks to Carl Menger and his two disciples Eugen von Böhm-Bawerk and Friedrich von Wieser. Schumpeter had the latter two as his teachers, and he also attended lectures in mathematics on his own. When Schumpeter received his doctorate in 1906, he was 23 years old and the youngest person to have earned this degree in the Empire.

After having traveled around for a few years and added to his life experience as well as to his knowledge of economics, Schumpeter returned in 1908 to Vienna to present his *Habilitationsschrift*. Its title was *Das Wesen und der Hauptinhalt der theoretischen Nationalökonomie* (1908; *The Nature and Essence of Theoretical Economics*), and it can be characterized as a work in economic methodology from an analytical perspective. In 1909, Schumpeter was appointed assistant professor at the University of Czernowitz and thereby became the youngest professor in German-speaking academia. It was also at Czernowitz that Schumpeter produced his second work, the famous *Theorie der wirtschaftlichen Entwicklung* (1912; second ed. from 1926 trans. as *The Theory of Economic Development*). At the University of Graz, to which he moved as a full professor in 1911, Schumpeter produced a third major study, *Epochen der Dogmen- und Methodengeschichte* (1914; trans. in 1954 as *Economic Doctrine and Method*). Over a period of less than 10 years Schumpeter had produced three important works, and one understands why he referred to the third decade in a scholar's life as "the decade of sacred fertility."

The Works from the Early Years

Das Wesen is today best known for being the place where the term 'methodological individualism' was coined. In its time,

however, this work played an important role in introducing German students to analytical economics, which Gustav von Schmoller and other members of the Historical School had tried to ban from the universities in Germany. *Das Wesen* is well written and well argued, but Schumpeter would later regard it as a youthful error and did not allow a second edition to appear. The reason for Schumpeter's verdict is not known, but it is probably connected to his vigorous argument in the book that economics must sever all links with the other social sciences.

While the emphasis in *Das Wesen* had been exclusively on statics, in his second book, *Theorie der wirtschaflichen Entwicklung*, it was on dynamics. Schumpeter very much admired Walras' theory of general equilibrium, which he had tried to explicate in *Das Wesen*, but he was also disturbed by Walras' failure to handle economic change. What was needed in economics, Schumpeter argued, was a theory according to which economic change grew out of the economic system itself and not, as in Walras, a theoretical scheme in which economic change was simply explained as a reaction to a disturbance from outside the economic system.

Schumpeter starts the argument in *Theorie* by presenting an economy where nothing new ever happens and that therefore can be analyzed with the help of static theory, that is, all goods are promptly sold, no new goods are produced or wanted, and profits are zero. Schumpeter then contrasts this situation of a 'circular flow' with a situation in which the activities of the entrepreneur sets the whole economic system in motion, and which can only be explained with the help of a dynamic theory. The model that Schumpeter now presented in *Theorie* would later be repeated and embellished upon in many of his writings: the entrepreneur makes an innovation, which earns him a huge profit, this profit attracts a swarm of other, less innovative entrepreneurs and as a result of all these activities, a wave of economic change begins to work its way through the economic system, a business cycle, in brief, has been set in motion. The theory of business cycles that one can find in *Theorie* is fairly rudimentary, and Schumpeter would later spend much time in improving upon it.

Much of Schumpeter's analysis in *Theorie* is today forgotten and few economists are today interested in the way that Schumpeter explains interest, capital, and profit by relating these to the activities of the entrepreneur. Some parts of *Theorie*, however, are still very much alive and often referred to in studies of entrepreneurship. In one of these, Schumpeter discusses the nature of an innovation, and explains how it differs from an invention; while an invention is something radically new, an innovation consists of an attempt to turn something – for example, an invention – into a money-making enterprise. In another famous passage, Schumpeter discusses the five main forms of innovations:

> (1) The introduction of a new good … or of a new quality of a good. (2) The introduction of a new method of production … (3) The opening of a new market … (4) The conquest of a new source of supply of raw materials or half-manufactured goods … (5) The carrying out of the new organization of any industry, like the creation of a monopoly position … or the breaking up of a monopoly position.

Schumpeter's description of what drives an entrepreneur is also often referred to, as is his general definition of entrepreneurship: "the carrying out of new combinations."

Schumpeter's third work from these early years is a brief history of economics, commissioned by Max Weber (1914–20) for a handbook in political economy (*Grundriss der Sozialökonomik*). Its main thesis is that economics came into being when analytical precision, of the type that one can find in philosophy, came into contact with an interest in practical affairs, of the type that is common among businessmen; and to Schumpeter this meeting took place in the works of the Physiocrats. *Epochen der Dogmen- und Methodengeschichte* was later overshadowed by the much longer *History of Economic Analysis*, but while the latter work tends to be used exclusively as a reference work, Schumpeter's study from 1914 can be read straight through and is also easier to appreciate.

Difficult Mid Years

By the mid-1910s, Schumpeter had established himself as one of the most brilliant economists in his generation, and like other well-known economists in the Austro-Hungarian Empire, he hoped for a prominent political position, such as finance minister or economic adviser to the Emperor. During World War I, Schumpeter wrote a series of memoranda, which were circulated among the elite of the Empire, and through which he hoped to establish himself as a candidate for political office. The various measures that Schumpeter suggested in these memoranda are of little interest today, for example, that the Empire must not enter into a customs union with its powerful neighbor, Germany. What is of considerably more interest, however, is that they provide an insight into Schumpeter's political views when he was in his early 30s. Schumpeter's political profile at this time can be described in the following way: he was a royalist, deeply conservative, and an admirer of tory democracy of the British kind.

Schumpeter's attempt during World War I to gain a political position failed, but his fortune changed after the Empire had fallen apart and the state of Austria came into being. In early 1919, Schumpeter was appointed finance minister in a joint Social Democratic and Catholic Conservative government in Austria led by Karl Renner. Already by the fall of 1919, however, Schumpeter was forced to resign, mainly because the Social Democrats felt that he had betrayed them and could not be trusted. The Social Democrats in particular thought that Schumpeter had gone behind their backs and stopped their attempts to nationalize parts of Austria's industry. Schumpeter always denied this, and in retrospect it is difficult to establish the truth. What is clear, however, is that the Austrian Social Democrats advocated a democratic and peaceful form of socialism, while Schumpeter detested all forms of socialism.

Loath to go back to his position at the University of Graz, Schumpeter spent the early part of the 1920s working for a small bank in Vienna, the Biedermann Bank. Schumpeter did not take part in the everyday activities of the bank, but mainly worked as an independent investor. These activities ended badly, however, and by the mid-1920s, Schumpeter was forced to leave the Biedermann Bank and had by this time accumulated a considerable personal debt. For many years to come, Schumpeter would give speeches and write articles in order to

pay back his debts. Adding to these economic misfortunes was the death in 1926 of his beloved wife Anna ('Annie') Reisinger, a 20 years younger working class girl to whom Schumpeter had only been married for a year. From this time on, Schumpeter's friends would later say, there was a streak of pessimism and resignation in his personality.

In 1925, Schumpeter was appointed professor of public finance at the University of Bonn, and it is clear that he was both pleased and relieved to be back in academia. While his ambition, no doubt, extended to politics and business, he always felt an academic at heart. The great creativity that Schumpeter had shown in the 1910s was, however, not to return in the 1920s, and Annie's death was no doubt an important reason for this. Schumpeter's major project during the 1920s was a book in the theory of money, but this work was never completed to his satisfaction (Schumpeter, 1970). Schumpeter did, however, write several interesting articles during these years, some of which are still worth reading. One of these is *The Instability of Capitalism* (1989), in which Schumpeter suggests that capitalism is undermining itself and will eventually turn into socialism. Another worthwhile article is *Gustav vs. Schmoller und die Probleme von heute* (1926), in which Schumpeter argues that economics has to be a broad science, encompassing not only economic theory but also economic history, economic sociology, and statistics. Schumpeter's term for this type of general economics is *Sozialökonomik*.

To illustrate what economists can accomplish with the help of sociology, Schumpeter wrote an article on social classes (1991c), which is still often referred to. Schumpeter starts out by drawing a sharp line between the way that the concept of class is used in economics and in sociology. In economics, Schumpeter says, class is basically used as a category (e.g., wage earner/non-wage earner), while in sociology class is seen as a piece of living reality. An attempt was also made by Schumpeter to link his theory of the entrepreneur to the idea of class.

In mentioning Schumpeter's articles on social classes, something must also be said about two of his other famous studies in sociology: *The Fiscal Crisis of the Tax State* (1918) and *The Sociology of Imperialisms* (1991b). The former study can be described as a pioneer effort in the sociology of taxation, which not only focuses on the situation in Austria just after World War I but also attempts to formulate some general propositions about the relationship between taxation and society. Schumpeter, for example, suggests that if the citizens demand more and more subventions from the state, but are unwilling to pay for these through ever higher taxes, the state will collapse. In the article on imperialism, Schumpeter argues that imperialism grows out of a social situation that is not to be found in capitalism, and whatever imperialist forms that still exist represent an atavism and a leftover from feudal society. Schumpeter's famous definition of imperialism is as follows: "imperialism is the objectless disposition on the part of the state to unlimited forcible expansion."

The Years in the United States

By 1930, Schumpeter was still depressed about his life and quite unhappy about his career; he had found no one to replace his wife on an emotional level and he felt that he deserved a better professional position than Bonn. When Werner Sombart's chair at the University of Berlin became vacant, Schumpeter had high hopes that he would get it. When this did not happen, however, he instead accepted an offer from Harvard University, and in 1932, he moved to Cambridge, Massachusetts, for good. Schumpeter was slowly to regain his emotional composure, and also his capacity to work, in the United States. In 1937, he got married to economist Elizabeth Boody, who regarded it as her duty in life to take care of Schumpeter and manage his worldly affairs. With the support of his wife, Schumpeter produced three major works: *Business Cycles* (1939), *Capitalism, Socialism and Democracy* (1942), and *History of Economic Analysis* (published posthumously in 1954).

The Works from the American Period

Of these three works, the one for which Schumpeter had the highest hopes was definitely *Business Cycles* (1939), which appeared exactly 25 years after his last book in Europe. This work is more than 1100 pages long and it traces business cycles in Great Britain, the United States, and Germany during the years 1787–1938. Schumpeter had hoped that *Business Cycles* would get the kind of reception that Keynes' *General Theory* got, and he was deeply disappointed by the lack of interest that his colleagues and other economists showed. The impression one gets from histories of economic thought, however, is that *Business Cycles* is rarely read today, mainly because few people are persuaded by Schumpeter's theory that business cycles are set off by innovations and that their motion can be best described as a giant Kondratieff cycle, modified by Juglar and Kitchin cycles; Schumpeter's handling of statistics is also considered poor. To a large extent this critique is true, although it should also be noted that a number of themes and issues in this and other of Schumpeter's works are increasingly being referred to in evolutionary economics.

After many years of excruciatingly hard work on *Business Cycles*, Schumpeter decided that he needed an easier task to work on than the recasting of economic theory that was on his agenda since the time in Bonn. In the late 1930s, Schumpeter therefore began working on what he saw as a minor study of socialism. This minor study, however, quickly grew in size, and when it finally appeared in 1942 – under the title *Capitalism, Socialism and Democracy* – it was nearly 400 pages long. Of all of Schumpeter's works (1942), this book was to become the most popular one, especially in the United States where it is still considered a standard work in political science. *Capitalism, Socialism and Democracy* has also been translated into more languages than any other work by Schumpeter, and it is still in print.

Capitalism, Socialism and Democracy contains an interesting history of socialist parties (part V), a fine discussion of the nature of socialism (part III), and an excellent discussion of the work of Karl Marx (part I). What has made this work into a social science classic, however, are its two remaining parts with their discussion of capitalism (part II) and the nature of democracy (part IV). Capitalism, Schumpeter says, can be characterized as a process of continuous economic change, through which new enterprises and industries are continuously being created and old ones continuously being destroyed.

Schumpeter's famous term for this process is 'creative destruction.' Perfect competition of the type that economists talk about, he also says, is a myth, and monopolies, contrary to common belief and economists' dogma, are often good for the economy. Without monopolies, for example, very expensive forms of research and investments would seldom be undertaken.

Schumpeter's theory of monopolies has led to a large number of studies of innovation. By 'the Schumpeterian hypothesis' two propositions are meant: that large firms are more innovative than small firms, and that innovation tends to be more frequent in monopolistic industries than in competitive ones. Each of these hypotheses can in their turn be broken down into further hypotheses. Many decades later, the results of all of these studies are still inconclusive, and there is no consensus if monopolistic forms of enterprise further or obstruct innovation (for an overview of research on the Schumpeterian hypothesis, see Kamien and Schwartz, 1982).

Schumpeter's overall theory in *Capitalism, Socialism and Democracy* – the idea that capitalism is on its way to disappear and be replaced by socialism – has, on the other hand, led to little concrete research. One reason for this is probably that many readers of Schumpeter's book have felt that his argument is very general in nature and at times also quite idiosyncratic. Schumpeter argues, for example, that capitalism tends to breed intellectuals, and that these are hostile to capitalism; that the bourgeois class is becoming unable to appreciate property; and that the general will of the bourgeoisie is rapidly eroding. "Can capitalism survive?" Schumpeter asks rhetorically, and then gives the following answer, "No. I do not think it can." Schumpeter's conclusion about the inevitable fall of capitalism has often been sharply criticized (e.g., Heertje, 1981). His more general attempt to tackle the question of how social and economic institutions are needed for an economic system to work properly has, however, remained unexplored. There also exists a certain tendency to cite catchy phrases from Schumpeter's work without paying attention to their organic place in his arguments.

What has always been much appreciated in *Capitalism, Socialism and Democracy* is Schumpeter's theory of democracy. Schumpeter starts out by criticizing what he calls "the classical doctrine of democracy," which he characterizes in the following way: "the democratic method is that institutional arrangement for arriving at political decisions which realizes the common good by making the people itself decide issues through the election of individuals who are to assemble in order to carry out its will." What is wrong with this theory, he argues, is that there is no way of establishing what the common good is. There is also the additional fact that politicians do not have interests of their own, according to this theory; their function is exclusively to translate the desires of the people into reality.

To the classical type of democracy, Schumpeter counterposes his own theory of democracy, which he defines in the following manner: "the democratic method is that institutional arrangement for arriving at political decisions in which individuals acquire the power to decide by means of a competitive struggle for the people's vote." Some critics have argued that Schumpeter's theory is elitist in nature, since democracy is reduced to voting for a political leader at regular intervals. This may well be true, and Schumpeter's theory of democracy no doubt coexists in his work with contempt for the masses. Regardless of this critique, however, Schumpeter's theory is generally regarded as being considerably more realistic than the classical doctrine of democracy.

World War II was a very trying time for Schumpeter since he felt emotionally tied to German speaking Europe, even though he by now was a US citizen. Schumpeter did not support the Nazis but like many conservatives felt that Communism constituted a more dangerous enemy than Hitler. Schumpeter's intense hatred of Roosevelt, whom he suspected of being a socialist, also put him on a collision course with the academic community in Cambridge during World War II. In his diary, Schumpeter expressed his ambivalence toward Hitler, Jews, Roosevelt, and many other things, and in his everyday life he more and more withdrew into solitude and scholarship. The War, in brief, was a very difficult and demoralizing time for Schumpeter.

From the early 1940s, Schumpeter started to work feverishly on a giant history of economic thought that was to occupy him till his death some 10 years later. He did not succeed in completing *History of Economic Analysis*, which was instead put together by Elizabeth Boody Schumpeter after several years of work. *History of Economic Analysis* is many times longer than Schumpeter's history of economics from 1914, and it is also considerably more sophisticated in its approach. Schumpeter's ambition with this work, it should first of all be noted, was not only to write the history of economic theory, but also to say something about economic sociology, economic history, and economic statistics, the four 'fundamental fields' of economics or *Sozialökonomik*. It should also be mentioned that *History of Economic Analysis* begins with a very interesting methodological discussion of the nature of economics. This is then followed by a brilliant, though occasionally willful, discussion of economics from classical Greece to the years after World War I. The section on twentieth century economics was unfortunately never completed, but it is clear that Schumpeter was very discontent with the failure of his contemporaries to create a truly dynamic economic theory.

Schumpeter died in his sleep on 8 January 1950, and the cause was put down as cerebral hemorrhage. Some of his friends thought that the real reason was overwork, while his diary shows that he had been tired of life for a long time. Schumpeter's private notes also show that behind the image of brilliant lecturer and iconoclastic author, which Schumpeter liked to project, there was a person who felt deeply unhappy with the way that his life had evolved and with his failure to produce a theory that would revolutionize economic thought. "With a fraction of my ideas," he wrote in dismay a few years before his death, "a new economics could have been founded."

Abstract

Alfred Schütz, born in Vienna, emigrated in 1938 via Paris to New York. He was founder of the phenomenological approach in sociology, which is one of the main paradigms in the *interpretative social sciences*. He formulated a theory of the life world and its structures showing how actors produce and understand social reality in everyday interaction and communication. His concepts initiated inquiry into the everyday life of societies (sociology of everyday life) and entered into the mainstream of sociological theory. His methodological suggestions sparked innovations in the field of qualitative methods of social research. Beyond sociology, his ideas were conceived in philosophy and in many fields of cultural sciences.

Vitae

Alfred Schütz was born in Vienna on 13 April 1899. Here, he studied law and social sciences from 1918 to 1921. After receiving his Doctorate of Law, he continued his studies in the social sciences until 1923. His teachers included Hans Kelsen, an eminent lawyer, Ludwig von Mises, and Friedrich von Wieser, prominent representatives of the Austrian school of economics. Equally important as his university studies was his participation in the informal academic life of Vienna, e.g., his participation in the private seminars of von Mises, where Schütz also cultivated his philosophical interests. In addition to his scholarly activities, Schütz held a full-time job as a bank attorney, a dual life that lasted until 1956. After the annexation of Austria to the Third Reich in 1938, Schütz and his family escaped to New York. On his arrival, Schütz got in touch with Talcott Parsons whose *Structure of Social Action* he intended to review. But despite their intense correspondence (Schütz and Parsons, 1978), the contact between Schütz and Parsons broke down. Instead, Schütz became affiliated with the Graduate Faculty at the New School for Social Research in New York where he started teaching as Lecturer in 1943, advancing to a full Professor of Sociology in 1952 and also of Philosophy in 1956. He died on 20 May 1959 in New York.

Major Aims of Schütz' Theory

Alfred Schütz' social theory focuses on the concept of the life world, which is understood as a social–cultural world as it is perceived and generated by the humans living in it. Schütz identifies everyday interaction and communication as being the main processes in which the constitution of the life world's social reality takes place. In this sense, his approach pursues two major goals: the development of a theory of action, which reveals the constitution of social reality with its meaning structure given in the commonly shared typical patterns of knowledge, and a description of the life world with its multiple strata of reality emerging from these constituting processes. These leitmotifs merge in a theory of life world constitution – a project which occupied Schütz during the final years of his life.

Main Intellectual Sources of the Schützian Approach

Schütz' conception originated in the intellectual discourse in the social sciences and philosophy of the early decades of this century. Schütz developed his position from within a triangular interdisciplinary field marked by Max Weber's historising interpretative sociology (*verstehende Soziologie*), the Austrian economic approach represented by Ludwig von Mises, and the philosophical theories of the stream of consciousness formulated by H. Bergson and E. Husserl. From the very onset, he adopted Max Weber's view of social reality as a meaningful social–cultural world, as well as his concept of social action as a meaning-oriented behavior, and shared Weber's search for an interpretative method in sociology. He also shared the methodological individualism advocated by Weber and by the Austrian economists who denoted individual action as the starting point of social research. At the same time, he accepted the need for a generalizing theory of action, as stressed by his teacher Ludwig von Mises, and criticized Weber for neglecting to develop the basic framework of such a theory and especially for not inquiring into the constitution of meaning attached to social action. But Schütz' criticism also addressed the 'general theory of action' based on an 'a priori' postulate of *rational choice* put forth by Ludwig von Mises. Schütz rejected this conception since it imposed an abstract framework on actors' orientation of action and ignored their actual stock of knowledge.

In order to analyze how the meaning attached to action is revealed, Schütz referred to the philosophical concepts of Henri Bergons and Edmund Husserl. Both offer insights into the stream of lived experience and into the acts of consciousness in which our world is meaningfully constituted. Schütz adopted the Bergsonian idea of the stream of consciousness in his first scholarly attempts in 1924–28 (Schütz, 1982), only to later recognize the difficulties in Bergson's intuitivism and to turn to Husserl's phenomenology, which ultimately gave the name to his approach. Husserl was concerned with the acts of consciousness, which establish the meaningful taken-for-grantedness of the world in humans' natural attitude. His term 'life world,' which Schütz later assumes, is aimed at the reality constituted in those acts. Based primarily on this philosophical approach, Schütz wrote his first monograph, *Der sinnhafte Aufbau der*

sozialen Welt, in 1932, in which he developed the basic concept of his theory (Schütz, 1932). Starting with the criticism on Max Weber mentioned above, he devoted himself to the process in which humans create the social world as a reality that is meaningful and understandable to them.

Theory of the Life World with Its Everyday Core

In order to grasp the constitution of the social world, Schütz (1932) had to transcend the realm of consciousness and perception analyzed by Husserl. He included both acts of consciousness as well as human action and interaction into the constitutive process under scrutiny. Departing from the transcendental philosophical approach, he developed his own *mundane* phenomenology, which analyzes the constitution of the meaningful reality within social relationships in the everyday world.

He proceeded in three steps dealing with three problems constitutive for any theory of action, which is searching for the construction of social reality.

1. How does a meaningful orientation of human action emerge?
2. How can we understand the Other?
3. How is socially shared, intersubjective valid knowledge generated?

Following the principle of methodological individualism, Schütz started with the analysis of single individual action. Relying on Bergson's concept of the inner stream of lived experience and on Husserl's investigations on intentionality and temporality of consciousness, Schütz first explored the constitution of meaning in subjects as a temporal process. The meaning attached to a lived experience emerges from successive acts of selective reflection aimed toward it and framing it into a context of other experiences. The schemes of experience on which the primary meaning of action, i.e., its project is based, arise from this basic temporal dynamics and plasticity of consciousness. The temporality of the meaning attached to an action manifests itself in two kinds of motivation attached to its different temporal dimensions: '*in-order-to-motives*,' which direct action toward the future, and '*becausxe-motives*' representing the roots of the action in the past. However, the meaning of the project of action changes during the time when the projected action is going on. The final meaning of an action can be found in the experience perceived by the subject when looking at the changes that have emerged in the meaning structure of the action when the action is completed. The meaning attached to an action and consequently the schemes of experience are thus not only affected by the acts of consciousness but also by the action itself.

In his second step, Schütz proceeded to show how the schemes of experience are shaped by interaction and communication. He perceived communication as a process in which two subjective streams of consciousness are coordinated within a social interaction (*Wirkensbeziehung*). Thus, communication signifies an interaction in which the meaning of ego's action consists in the intention to evoke a reaction of the alter ego. Actions in this sense have the function of signs, which are mutually indicated and interpreted. The ultimate meaning of my action is revealed in the reaction of the Other and vice versa, therefore communication generates a *chain of motives* where my *in-order-to-motives* become *because-motives* of the Other and provide a common stock of shared patterns of interpretation, which allows for mutual understanding even if each of the actors are always referring to their own schemes of experience. In this concept of understanding, based on interaction, Schütz offers his own solution to the problem of intersubjectivity posed by Husserl.

The constitution and appropriation of shared knowledge primarily takes place in long lasting face-to-face interaction (we-relations) where the mutual expectations are learned, verified, and sedimented to typical patterns that can be applied to more remote and anonymous strata of the social world. As a result, the meaning structure of the social world is characterized by *typifications* of actions, situations, and persons generated in interaction and communication.

In these three steps, Schütz laid down the main features of his theory of the life world. In his later work, Schütz (1962, 1964, 1966) determined this communicatively created social reality as the world of everyday life, in which typical patterns are taken for granted, and which represents the intersubjective common core of the reality we live in. Later on (Schütz, 1962, 1970), he disclosed further structural characteristics of this everyday core of the life world. Since its typical structure greatly depends on action, it is also the pragmatic orientation selecting the areas where typification processes take place. Both typicality and this kind of selection, which Schütz designated as *pragmatic relevance* (Schütz, 2003), represent two generative principles of order in the everyday world. They determine its formal structure and at the same time, when realized in action, they shape this structure into a concrete social–cultural world, which is thus characterized by social distribution and differentiation of knowledge. A third moment structuring the everyday world can be found in the rootedness of its constitution in individual action. Here actors and their bodies represent the central point of the *everyday world and its temporal, spatial, and social dimensions* that are arranged into spheres of past and future, of within-reach and distant and of intimacy and anonymity, respectively, to the actors' own position (Schütz and Luckmann, 1973).

Everyday reality is nevertheless not identical with the life world on the whole. By suspending their pragmatic interests, actors are able to modify their everyday experiences and perceive them as objects of a game, fantasy, art, science, or, if the conscious attention is completely absent, as a dream. There are areas – even in the realm of everyday action directed by the principal of pragmatic relevance – which are beyond the sphere of actors' everyday practice and therefore transcend it. All these modifications represent different provinces of meaning transcending the everyday world and constituting *multiple realities* (Schütz, 1962), which make up the life world. Nevertheless, among the different provinces of the life world, the everyday core denotes a *paramount reality* since it is only here that actors, driven by the *fundamental anxiety* when facing the finality of their lives, have to master their living conditions and are engaged in communicative processes producing common knowledge, which makes mutual understanding possible.

Schütz (1962) viewed communication as a substantial constitutive mechanism of social reality and stressed the role of *language* in this process. He considered language – including its syntax and semantics – as an objectivation of sedimented, social provided stock of knowledge that preserves relevances and typification inherent to cultures and social groups, and thus as crucial for the constitution of the life world (Schütz and Luckmann, 1989). Schütz saw language as delineating an essential case of social objectified systems of appresentation, which bridges the transcendence between different areas and meaning provinces of the life world. Another important integrative mechanism in the life world are symbolic structures, which are often based on language, and intermediate between the everyday world and noneveryday realities such as religion, arts, or politics (Schütz, 1962).

Schütz did not restrict his study of the structure of the life world solely to theoretical research. He also applied his theory as a general interpretative scheme to several social fields and problems. He explored courses of intercultural communication and the social distribution of knowledge, the social conditions of equality in modern societies as well as the fields of music and literature (Schütz, 1964, 1982; Embree, 1998).

Consequences of the Theory of Life World for the Methodology of the Social Sciences

Schütz considered the construction of ideal types to be the general methodological device in the social sciences since sociology, economy, political science, etc., explain social phenomena by modeling ideal actors and courses of action, which they endorse with special features as explanatory variables. However, he did not see ideal types in the Weberian sense, i.e., as a scientific model, which does not need to correspond to reality in all respects. For Schütz, the ideal-typical method is legitimized by his findings on the typicality of everyday world, which is the object of social research. Social reality can be approached by type-construction on the scientific level because its immanent structure is typified itself. Thus, the Schützian theory of the life world and its structures represents a methodological tool to bridge the gap between sociological theoretical reasoning and its object. The methodological rule, which Schütz derived from his theoretical approach consists correspondingly in the *postulate of adequacy* (Schütz, 1962, 1964) between everyday and scientific typifications. This postulate holds that ideal types featured by the social sciences have to be constructed in correspondence to the structure of the everyday typifications, so that everyday actors can take the model for granted when they act under the conditions stated in the ideal type. In this sense, social scientists as well as everyday actors have to follow the same frame of reference given by the structure of the life world but their cognitive attitude differ in several respects: scientists neither share the pragmatic interest of everyday actors nor do they share their everyday rationality restricted by their beliefs in the grantedness of typical knowledge. Opposing T. Parson's functionalism and C.G. Hempel's methodologic positivism, Schütz (1962) stressed that scientists must not impose their own theoretical concepts and rationality on their object of study – the life world. First, they must discover and then respect its immanent meaning structure.

The Significance of the Schützian Approach for the Social Sciences

Since the 1960s, Schütz' theory has drawn sociologists' attention to inquiries into everyday interaction, communication as well as to the insight that social reality has to be considered as a construction produced within these processes. Sociologists started to examine the practices of everyday action, communication, and interpretation from which social reality emerges. Garfinkel's (1967) *Ethnomethology*, which was aimed at finding the formal properties of everyday practices, led to a series of case studies covering a wide range of everyday life in society and its institutions. Continuing this line of research, examinations of everyday communication were provided by Schegloff (2007) and Sacks (1995), whose *Conversational Analysis* became a widespread method in qualitative sociological research. A. Cicourel's (1964) *Cognitive Sociology* revealed the constructed character of data in social institutions as well as in science and thus initiated a series of studies in the sociology of organization and in the sociology sciences. *Milieus* as formations of everyday interaction are the subject of the *Social Phenomenology* R. Grathoff (1986).

P.L. Berger and Th. F. Luckmann's (1966) idea of *the Social Construction of Reality* (as being a general process in which cultural worlds emerge) triggered new impulses in both the sociology of knowledge and the sociology of culture reconceived now in Schützian terms. In this context, Schütz' impact can also be seen in the sociology of language and the sociology of religion (Luckmann, 1962, 2002). Contemporary Marxian theory saw the way in which Schütz focused on the everyday practice as a possible mediation between social structure and individual consciousness. The term *phenomenological sociology* was coined in the 1970s (Psathas, 1973) to address the spectrum of approaches oriented and inspired by Schütz' theory. Under this label, Schütz' approach became one of the general paradigms in the interpretative social science and theory of action. The diffusion and empirical application of the Schützian approach enforced the search for qualitative research methods, which would reveal data pertaining to the social construction of social reality in everyday life. Aside from ethnomethodology and conversational analysis mentioned above, this quest especially led to a development of methods in the fields of the ethnography of everyday life (Honer, 1993), social hermeneutics (Soeffner, 1989; Hitzler et al., 1999) as well as to a refinement in the techniques of narrative interviews and in biographical research (Rosenthal, 2005).

Once established in the 1970s, the Schützian paradigm influenced the mainstream of sociological theory, which became sensitive not only to the social construction of life world but also to the phenomenological background of the Schützian theory. The 'life world,' in the sense of a basic social reality provided by humans in their 'natural' intercourse,

became one of the central terms in social theory (Habermas, 1981). The everyday construction of social reality was recognized as a crucial mechanism in which society emerges (Bourdieu, 1972; Giddens, 1976; Bauman, 1991). The phenomenological conception of meaning constitution reformulated as an *autopoiesis* (self-creation) of social and psychic systems influenced the development of the contemporary sociological system theory (Luhmann, 1996).

Beyond the scope of sociology, other humanities also gained innovative impulses from the Schützian approach. In philosophy, Schütz' theory led to a critical assessment of the Husserlian view of intersubjectivity and to the conceptions of a *worldly phenomenology* (Embree, 1988) or of a *philosophy of modern anonymity* (Natanson, 1986). In the literature, Schütz' constructionism inspired the *esthetics of reception*, which pointed out the beholder's participation in cocreating the autonomous reality of literary works (Jauss, 1982). Schütz' concept of the structure of life world also affected theorizing in social geography (Werlen, 1993), educational theory (Meyer-Drawe, 1984), and political science (Voegelin, 1966). New editions of his writings (Schütz, 2003–2013, 2011) as well as the recent studies on his intellectual biography (Endreß, 2006; Barber, 2004; Nasu et al., 2009), both based on his literary estate, reveal that wide scope of Schutz' scientific impact.

Abstract

Aimed at a contemporary view of science and development that takes into account changes brought about by information and communication technologies, this article examines why low-income countries are in pursuit of the 'Western way of knowing' known as science. Toward this aim, several perspectives are reviewed: modernization, dependency and world systems, neoinstitutional, global systems, postcolonialism, and reagency. The intent is to highlight how each casts the nature of science and its relation to the project of development.

Introduction

Macrolevel orientations in the sociology of science and in the sociology of international development and social change have alluded to the connection between science and development because national economic growth and scientific capacity (i.e., knowledge production, technological development, technical innovation, and scientific discovery) are empirically associated with each other (Castells, 2000; Grammig, 2002; Malmgren et al., 2010; Schofer, 2004; Schofer et al., 2000). For example, scientific knowledge production and technological development are almost always monopolized by economically powerful countries, such as the Group of Seven and the Organization for Economic Cooperation and Development countries (Bradshaw et al., 1993; Castells, 2000; Gereffi and Fonda, 1992; Migdal, 1988; Sernau, 2012). Countries in Africa (with the exception of South Africa), Asia (with the exception of Japan, Singapore, South Korea, and Taiwan and more recently China and India), and Latin America (with the exception of Argentina, Brazil, and Mexico) have almost always been consumers of but never producers of knowledge, innovation, and technology; beneficiaries of technology transfer programs and initiatives but rarely benefactors. However, when knowledge, innovations, and technologies travel, or are exported to travel from their production sites in developed countries to test sites in developing countries, more often than not these packages of Western knowledge have proved largely ineffective, insensitive to, and incompatible with local needs, and have all too often resulted in a dependent and the uneven development of countries at the periphery of the global economic system (Bradshaw, 1988; Grammig, 2002).

Macrolevel data from the United Nations Development Programme indicate that countries at the high human development level have, on average, about 2335 scientists, technicians, and engineers per million people. Countries at the medium human development level have, on average, about 588 scientists, technicians, and engineers per million, while estimates are not available for countries at the low human development level (UNDP, 2003). Implicitly, these numbers indicate that science and technology are indispensable tools for national competitiveness and hegemony. Indeed, the geography of scientific and technological capacity has a major impact on the centers and networks of global society (Castells, 2000). With the goal of coming up with a contemporary view of science and development that takes into account the changes and shifts brought about by new information and communication technologies (ICTs), this article attempts to explain why developing countries (i.e., low-income countries or peripheral countries) are so enmeshed in pursuing a 'Western way of knowing' called science. Toward this goal, several theoretical perspectives are presented: modernization, dependency/world systems, institutional, global systems, postcolonial, and reagency. The intent is to show how each perspective views the nature of science. Toward the end, the authors propose a perspective that takes into account the changes and recalibrations in the logic (i.e., spatial and temporal) of social interaction resulting from the 'time–space compression' brought about by advances in ICT (Castells, 2000, 2001).

Modernization Theory

Modernization theory casts development as a uniform evolutionary route that all societies follow, from agricultural, rural, and traditional societies to postindustrial, urban, and modern forms (Bradshaw, 1987; Escobar, 1995; Chirot and Hall, 1982; Shrum, 2000). In other words, all societies, once engaged in the modernization process, follow a predetermined sequence of developmental stages: traditional economies, transition to takeoff, takeoff itself, drive to maturity, age of high consumption, and postindustrial society (Chirot and Hall, 1982: 82). Modernization theory emphasizes internal forces and sources of socioeconomic development such as formal education, market-based economy, and democratic and secular political structures. Although modernization theory does not rule out external forces and sources of social change and economic development, it focuses less on foreign influences (Jenkins and Scanlan, 2001; Shrum, 2000).

Among external influences, however, science is exceptional because it is considered beneficial to developing countries by way of 'knowledge and technology transfer' from developed countries (Shrum, 2000). In other words, societies can be

fast-tracked to modernization by 'importing' Western technical capital, forms of organization, and science and technology to developing countries (Herkenrath and Bornschier, 2003; Shrum, 2000). W.W. Rostow argues that adoption of scientific methods and scientific ways of thinking and acquisition of technoscientific skills are critical at the 'transition to takeoff' stage of development (Chirot and Hall, 1982). Essentially, proponents of modernization theory view science and technology as catalysts for development. Science and technology provide conducive environments for economic growth in developing countries through their ability to provide rational protocols in decision making for the efficient use of material and human resources (Shrum and Shenhav, 1995).

As far as modernization theory is concerned, development is simply a matter of knowledge and technology transfer that is unproblematic and straightforward, context free, and not disruptive of existing social and cultural arrangements in developing countries (Herkenrath and Bornschier, 2003). Modernization theory also seems to be unmindful of the fact that much of the knowledge and technology critical for national development and national competitiveness are within the domain of proprietary knowledge production. In a way, modernization theory implies a monolithic, one-way, and top-down development scheme that holds true for all identities, for all time, for all places, and for all contexts. The same holds true for knowledge generation, production, dissemination, and representation. In this top-down development model, the sources of knowledge are foreign to the places and identities to which knowledge is applied or exported. As a model for social change and development, modernization theory fails to consider the possibility of having an interactive and multifarious process of knowledge generation and exchange, which is made possible by recent advances in ICT.

As far as modernization theory is concerned, science is seen as exceptional and different from other institutions in Western developed countries, and is assumed to be independent of and invariant to the limitations of contexts of interpretation and use, and further is viewed as a search, by means of generating objective and rational knowledge claims, for empirical truths and universal laws. Such casting of science is reminiscent of the limited translation model that Callon (1995) critiques. In other words, modernization theory emphasizes the beneficial role of objective, rational science in national socioeconomic development. It de-emphasizes science's possible higher order and negative interactional effects upon local contexts and the identities that populate such contexts.

Dependency and World Systems Theory

Modernization theory stresses the importance of internal, local, and native factors as catalysts for socioeconomic development while making science – an external agent of change – an exception (Chase-Dunn, 1998; Shrum and Shenhav, 1995). Dependency theory (with its three main strains, classical dependency, dependent development, and mature dependency) and the more encompassing world systems theory both stress the important role of external and foreign factors in the development of underdevelopment (Bradshaw, 1987, 1988; Jenkins and Scanlan, 2001). Proponents of dependency theory contend that linkages and relations with developed countries, particularly when mediated by multinational corporations, are a means of control, domination, and exploitation that stifle and stunt economic growth and social development in developing countries (Bradshaw, 1988; Chirot and Hall, 1982; Herkenrath and Bornschier, 2003).

In contrast to the world systems approach, dependency theory focuses on individual countries or nations: their role as sources of raw materials and cheap and disempowered labor, their relegation and assignment to a primary sector type economy, and their functions as markets for high-tech and expensive products of developed countries (Chase-Dunn, 1998; Shrum, 2000). These asymmetrical ties between core (or developed) and peripheral (or developing) countries result in the stunted socioeconomic development of the latter due mainly to the unequal balance of payments and trade. Classical dependency theory states that underdeveloped nations remain dependent because foreign investment in raw material extraction results in highly specialized, low value-added, export-oriented activities that impede the internal structural differentiation necessary for sustainable development (Bradshaw, 1988; Firebaugh, 1992).

A variant of dependency theory known as dependent development theory is characterized by its focus on a triple alliance of foreign capital, domestic capital, and the domestic state (Bradshaw, 1988; Bradshaw et al., 1993; Jenkins and Scanlan, 2001). Dependent development qualifies the argument of classical dependency. It contends that structural dependency on foreign (direct and indirect) investments and foreign markets in the developed countries constrains and distorts, but is not inconsistent with development. Rather, this type of dependency simultaneously triggers rapid economic development in the domestic cores and increasing economic disparities in the domestic peripheries of developing countries.

What is sometimes called mature dependency is exhibited by developing countries that are dependent on foreign – direct and indirect – investment (Bradshaw, 1988; Bradshaw et al., 1993). The nature of this dependency is indicated by the negative relationship between foreign investment and long-term economic development of developing countries. Castells (2000) and Escobar (1994) contend that the advent of new digital technologies results in a new form of dependency of technologically lagging nations on leading nations in ICT development. For these analysts, there is a need to recalibrate the economic and the political relations between developed and developing countries in a cyber economy and society.

Wallerstein's world systems theory focuses on the supra-macronetwork of societies in the modern and industrialized core, the traditional and impoverished periphery, and a group of semiperipheral countries in which mobility and position within the world system is conditioned by the capital, labor, resources, and constraints confronted by distinct sets of nations (Chase-Dunn, 1998; Gereffi and Fonda, 1992; Wallerstein, 1974). This system can be viewed as an international division of labor with the economies of semiperipheral and peripheral countries controlled by the core countries. With their

emphasis on the production of primary, low value-added products, the unchecked economic influence of multinational corporations, and the political power wielded by local capitalist agents, peripheral economies continue to have high levels of socioeconomic inequality, coupled with low levels of democracy and economic growth (Shrum, 2000). This perspective posits that a nation's location and incorporation into the capitalist world economy are the key determinants of national development outcomes (Gereffi and Fonda, 1992).

For Shrum (2000), an interesting point in the dependency/world systems account is that it is naïve to construe science as benign or neutral. When fostered by foreign investments brought in by multinational corporations into developing countries, science translates into one of a group of institutions that contribute to the development of 'sustained underdevelopment' in developing countries (Bradshaw, 1988; Shrum, 2000). Science is seen as part of an aggressively debilitating 'social cancer' when it is generated in core countries and then introduced into peripheral countries. As a case in point, scientific activities are disproportionately concentrated in core countries, and most such activities are conducted for the benefit of those countries, with applications directed at advancing their political hegemony and economic interest. The invention, patenting and production of technical innovations and process for maximal profit by core countries (and international corporations headquartered in them) typically go with the introduction and diffusion of commodities that are often inconsistent with the needs and conditions in peripheral countries, serving to draw raw materials and scarce resources away from more pressing developmental activities (Bradshaw, 1988; Shrum, 2000). Indeed, within the theory of dependency/world systems, science is a vehicle for world economic domination and for the maintenance of geopolitical hegemony of agents in the core countries.

Dependency/world systems theory explanations of the link between science and development are derived from both neoclassical and Marxist economics. On the one hand, neoclassical economics contends that knowledge producers are very much like capitalists who are driven by rationality and are oriented toward maximizing personal profits and extrinsic rewards. On the other hand, Marxist economics contends that knowledge producers are not only interested to produce knowledge for its own sake, but also to produce knowledge in research areas where profits and rewards are high. Granted, it is then logical to argue that knowledge producers play an important background role in the maintenance of dependency between core and peripheral countries, or between developed and developing countries. Knowledge producers comprise the needed technoscientific workforce that would facilitate the conversion from basic to applied knowledge. This conversion serves as the critical precursor for the creation and production of proprietary science and technology, which ultimately make up the essential components of foreign direct and indirect investment made by multinational corporations in developing countries. These investments facilitate the conversion of resources – using cheap, disempowered, and typically feminized labor – to commodities. Hence, it is reasonable to assert that the dependency/world systems theory's view of science is in sync with Callon's (1995) competition view in which the knowledge production process is driven by rationality, profit generation, and the accumulation of extrinsic rewards.

Neoinstitutional Theory

In its attempts to explain why developing countries are so much involved in the adoption and expansion of science – despite its generally unpredictable consequences – neoinstitutional theory calls attention to the role of international economic and financial organizations such as the International Bank for Reconstruction and Development (World Bank), International Monetary Fund, United Nations Education, Science, and Cultural Education, and other multilateral organizations (Schofer, 2004; Shrum, 2000). According to Schofer (2004), international organizations espouse science and encourage its dissemination in developing countries by deploying rhetoric to the effect that science is a core instrument for development (Drori et al., 2003). Indeed, much of the involvement of developing countries is founded on a belief in the universality of science as means to national socioeconomic development.

This belief, which inspired the institutionalization of science, has been introduced by Western development experts, propagated through technical assistance programs and monetary lending policies of international economic and financial institutions, affirmed in development plans and discourse, supported by international policy makers, and transmitted through Western education systems (Schofer et al., 2000; Schofer, 2004). Two closely related processes that give real force to the faith in science as an instrument for national socioeconomic development are those of professionalization and of institutionalization (Escobar, 1995; Schofer, 2004). The first refers to a process that draws developing countries into the politics of expert knowledge and Western science; the second refers to the creation of institutions (e.g., development banks such as the Asian Development Bank and the African Development Bank) from which discourses about development are formulated, generated, and disseminated to developing member countries (Escobar, 1995).

In essence, neoinstitutional theory is an account of the emergence, morphology, and expansion of academic and government research sectors as they become successful organizations in developed countries (Shrum, 2000). These organizations serve as models for developing countries to adopt in order for them to achieve the high levels of social and economic development characteristic of advanced Western societies. Neoinstitutional theory's construction of the nature of science is a hybrid of an objective and rational view with Callon's (1995) perspective on science as competition. It argues that scientists, experts, and scientific communities are principal exponents of universalism, espousing the idea of a global, universal, and context-independent science system (Shrum, 2000). Although neoinstitutional theory does not stress conflict, or the power and interests of actors, it describes processes fueled by competition.

As an explanation of why countries are so much dedicated to and involved in scientific pursuits, neoinstitutional theory is

enlightening because it identifies yet another factor external to a country – not multinational corporations in this case, but international economic and financial institutions – that triggers the spread and expansion of science in developing countries while legitimizing and reinforcing the idea that science is tantamount to development.

Global Systems Theory

Modernization theory emphasizes intranational (domestic and internal) forces, processes, structures, and organizations as influences on socioeconomic development. In contrast, dependency or world systems and institutional theory emphasize international (foreign and external) forces, processes, structures, and organizations. Despite their differences, these perspectives explain development through a nation-centric approach. They focus on the authority and power of the nation-state in effecting social change, and utilize nation-states as the units of analysis (Sernau, 2012). Furthermore, these perspectives assume the dominance of 'linear time' over 'space of place' – a dominance that contemporary social theorists claim is typical of social perspectives prior to the advent of ICTs (Castells, 2000; Sklair, 2000).

In contrast, global systems theory emphasizes transnational forces, processes, linkages, and organizations – which cross national borders but do not derive power and authority from actors and organizations associated with the nation-state – as forces configuring socioeconomic development (Bradshaw et al., 1993; Pinnington and Gray, 2007; Sernau, 2012). Linkages refer to transnational economic linkages, examples of which are foreign aid, foreign trade, foreign direct investment, and foreign loans (Bradshaw et al., 1993). Social theorists such as Castells (2000), Sassen (2000), and Sklair (2000) describe contemporary global society as transnational in nature, with a spatial logic that follows the 'space of flows' instead of the 'space of place,' and with a temporal logic that follows 'random time' instead of 'linear time.' According to these theorists, such shifts and recalibrations in the fundamental logic of social interaction are consequences of ICTs' capacity for high-speed communication and high-quality information exchange among globally dispersed actors, groups, and organizations.

Global system theory posits that contemporary economic and social inequalities are moving away from the traditional divisions among nations – core, semiperiphery, and periphery – and societal sectors – urban, suburban, and rural (Bergesen and Bata, 2002; Sassen, 2000; Sklair, 2000). Instead, inequalities are shifting toward a divide between membership and nonmembership in what is now called the transnational capitalist class (TCC), or the 'globally coordinated elite' (Sklair, 2000). The TCC is situated in and identified with no particular nation, state, or country; instead, it derives and exercises power and authority through transnational corporations (TNCs), and pursues resources – material and human – all over the world in its insatiable desire for profit and capital accumulation on a global scale (Evans, 2005). As a class, TCC comprises corporate executives, globalizing bureaucrats and politicians, globalizing professionals, and consumerist elites (Castells, 2000; Sklair, 2000). In the global economy, TNCs increasingly erode or circumvent the power of the state. This means that such transnational actors stand in an increasingly objective global position with respect to other global classes as opposed to the social classes within nation and states (Bergesen and Bata, 2002).

In other words, socioeconomic development is very much a function of whether an actor (in this case, an individual, a group, or an organization) is tied to the network structure of the TCC. This network structure comprises actors who possess capital (i.e., cultural, organizational, political, and technoscientific capital) that is critical for advancing the interests of the TCC. It is important to note that the possession of such capital is a necessary condition for an actor to be connected to the network structure. The network structure also consists of connections that serve as global channels for the movement of data, information, knowledge, and resources necessary for the further accumulation of wealth by the TCC. Hence, actors outside this network structure constitute an emerging domain called the global periphery, while actors connected to this network structure comprise the global core.

This account views science as a global network that relies on communication among scientists and other key actors around the world, wherein ICT expansion contributes to the formation of a global scientific community (Castells, 2000). However, despite the globality of science, its orientation and practice are geared toward the concerns and interests of the TCC (Castells, 2000; Sklair, 2000). In other words, global systems theory frames the nature of science as globally networked and coordinated, generated and produced by actors within science, influenced and configured by actors outside science, and generally oriented toward and distributed according to the interests and goals of the TCC. In essence, global system theory assumes the nature and dynamics of science to be uniform across network sites (i.e., localities and levels) and resistant to the social and cultural influences of localities.

As for ICTs' role in the formation of a global scientific community, this account assumes that such technologies have a uniformly enhancing effect on the content and intensity of communication, collaboration, productivity, and visibility of scientists in different network sites. However, recent studies on scientific research systems at the global periphery criticize these characterizations of contemporary science for being too one-dimensional, shallow, and devoid of empirical substantiation. Such criticism deserves serious attention in light of recent findings that transnational scientific collaboration and productivity do not immediately follow or result from ICT expansion and adoption at the global periphery. Despite the rapid diffusion of ICTs in peripheral areas, scientists' communicative behavior, collaboration patterns, professional networks, and research productivity are largely shaped by cultural, organizational, social, and sectoral contexts (Duque et al., 2005; Ynalvez et al., 2005, 2010).

Postcolonialism and Reagency

Postcolonial theory challenges the entrenched assumption that Western knowledge – as manifested by Western science and

technologies (broadly construed as idea systems, initiatives and projects, and technical artifacts) – is authoritative, objective and unbiased, reliable, universally applicable, and value-free (Anderson, 2002; Anderson and Adams, 2008). Like proponents of global systems theory, postcolonial theorists shy away from analyzing, critiquing, and framing science and development from a macrolevel, state-centered vantage point. Unlike global systems theory, proponents of postcolonial theory are hesitant to focus heavily on transnational forces, institutions, linkages, and processes, such as on the role of transnational networks. Instead, they emphasize new ways to examine the politicoeconomic dimensions of science and social change; the mutual and reciprocal reorganization between the global and the local; the increasingly global flow of cultures, information, people, practices, and technologies; and debates about intellectual property (Anderson, 2002).

An example of postcolonial theory is the work of Helen Verran (2002), who juxtaposes and describes two different Australian knowledge bases – among indigenous people and Western scientists – about firing strategies – practices for restoring land with controlled burns – with the intent of enhancing opportunities and increasing possibilities of cooperation and understanding between these two distinct groups with their very different ways of knowing. Indeed, postcolonial theory attempts to do so, without demarcating geopolitical boundaries between nation-states and empires – demarcations that have occupied central roles for casting and understanding social change – and pushes vigorously for a focus on 'contact zones' (Pratt, 1992). Contact zones are not geographic places with stable and symbolic meanings. Instead, they represent attempts at hegemony, but are – at the same time – sites of multivocality: of negotiation, borrowing, exchange, and interaction; and of redeployment, redefinition, reversal, and even reagency (Gilbert Joseph, quoted in Anderson, 2002; Shrum, 2005; Ynalvez et al., 2010). In other words, as a perspective for understanding science and development, postcolonial theory has the potential to explain how scientific endeavors become sites for generating and linking local and global identities, as well as sites for disrupting and challenging the distinction between the global and the local (Anderson, 2002; Anderson and Adams, 2008).

Most recently, the field of science and technology studies has seen the emergence of a reagency perspective from a long-term collaboration by a group of investigators in Africa and Asia. Unapologetically contrary to the very notion of development (Ynalvez et al., 2010), the original idea of reagency was a sensitizing concept based on the analogy with a chemical reagent – initiating certain kinds of reactions, often unpredictable. In the context of low-income areas, development on the ground is generally a resource intervention that stimulates chains of encounters, but without direction or progress in any determinate sense (Shrum, 2005). Reagency studies tend to focus on scientific and technological networks, donors (multinational and bilateral), and nongovernmental organizations that initiate programs and projects with explicit stories of making a difference, sustainability, and local participation.

The reagency perspective views development as a network of actors and encounters where knowledge, agendas, initiatives, and programs move across geographical boundaries (generally from higher to lower income areas) generating resource flows, bits of microorganization, and stories Shrum (2005); Ynalvez et al. (2010), Shrum et al. (2010). Illustrating this approach is a study by Harsh et al. (2010) that examines the implications of resource chains for nongovernmental organizations with projects in Kenya. Using the logic of reagency, they examine the difficult strategic choice faced by agencies and programs between targeting particular aid recipients (with massive inefficiencies) or efficient distribution of resources (with wildly divergent flows). Reagency shares the critical focus on the combined strength of human and nonhuman actors made famous by actor network theory (Latour, 2005). Rejecting such essentializing concepts as hegemony, center, and periphery, as well as the idea of an organized TCC, reagency understands social processes as local clusters of encounters and knowledge as an unproblematized set of stories. It provides science and technology studies with a concept and framework that emphasizes the unexpected results that come about from the interaction of initiatives and programs with local contexts, identities, and meanings.

Conclusion

Based on the foregoing review, the authors propose an approach to science and technology studies that takes a more 'situated' investigation of the connections between science and development. This emergent approach is essentially a hybrid between global systems theory and reagency, with some qualifications and alterations. Although this hybridized approach focuses on concrete transnational movements of capital, culture, knowledge, and technological innovation, it expresses caution in assuming global uniformity in the dynamics, nature, orientation, style, and practice of science. It rejects the assumption of uniformly positive impacts of ICTs on scientific communication, collaboration, networking, and productivity across localities with varied and distinct cultural, economic, historical, political, and social configurations.

In contrast to modernization, dependency or world systems, and neoinstitutional theories, this hybrid approach questions the following assumptions about development, knowledge production, social networks, and ICT diffusion at the global scientific periphery: (1) that development is a unidirectional, monotonic process of socioeconomic change that faithfully traverses certain trajectories; (2) that the diffusion of ICTs has globalized science, through networking and collaboration between knowledge producers from the core and periphery (Escobar, 1995; Shrum, 2000). Instead, what occurs as knowledge and technologies travel from one place to another is better described by the concept of reagency than by the ideologically loaded concept of development.

Whatever the approach to science and development, an important, unanswered question does center on the role of new ICTs in the process of research. The conventional view is that the diffusion of ICTs will generate the kinds of network shifts that have been characterized as globalization. But empirical findings on global research networks are mixed (Shrum, 2005: Ynalvez and Shrum, 2011; Ynalvez et al., 2010) and one lacks

convincing generalizations to characterize changes in cross-national networks brought about by new media. In time, some homogenization might occur, but shifting patterns in the global research network characterize the past 20 years. Actors in the outer space of science (Shrum et al., 2010) are more heterogeneous and disinterested than one may wish to contemplate.

Science and Law

Sheila Jasanoff, John F. Kennedy School of Government, Harvard University, Cambridge, MA, USA

Abstract

This article reviews scholarship on the nature and implications of the law–science relationship. Four major themes are identified: first, how the two institutions are thought to shape the authority structures and practices of modernity; second, how law affects the emergence and professionalization of scientific and technical disciplines; third, the role of expert witnesses and rules governing the admissibility of expert testimony; and fourth, how law functions as a site for generating new scientific knowledge and technical expertise.

The relationship between law and science has occupied scientists and philosophers since the early modern period, but in the twentieth century it also became a topic of social analysis and policymaking. Law–science interactions are significant for the social and behavioral sciences in two respects. First, because of their foundational role in modern social order, law–science interactions have emerged as a distinct branch of social science inquiry, though not one that can be encompassed within a single disciplinary envelope. Studies on this topic derive in the first instance from scholars and practitioners of law, but also from neighboring fields such as anthropology, sociology, and increasingly science and technology studies. Second, the intertwining of these two institutions affects developments in science as well as society, including the sciences of human behavior and action. These developments in turn have prompted investigation and critique by analysts of scientific knowledge in the making.

Three long-held presuppositions had to be set aside in order to position law–science relations within the scope of social science inquiry: first, that science represents 'truth to nature' and hence has no significant sociality; second, that law itself is, or should be, a science; and, third, that science and law operate independently of one another. Science was seen by its early practitioners as the effort to discern and reveal laws inherent in nature – in effect as god's laws, hence universal, immutable, and true. In time, law came to be seen as an institution in need of rationalization, to be made more like a science if possible in order to avoid arbitrary outcomes. For much of the twentieth century, too, legal theorists and practitioners regarded law and science as independent institutions, each with its own objectives, ethos, organization, and practices. Similarities and differences between the two fields preoccupied many observers, with frequent commentary on misalignments between law's demand for justice and science's commitment to truth.

By the end of the century, however, the role of human agency in making both science and law became more apparent, as did the interdependence of the two institutions. A new focus on the law's instrumental uses of science, and more generally expertise, led to divergent schools of thought about the epistemological status of scientific evidence. Those views in turn influenced thinking about how legal institutions should interact with scientific and technical experts. An onslaught of technically complex litigation caused judicial systems to reassess the rules of evidence. Analysts of the legal process grappled with wider questions about the role of the jury (in common law countries), the proper qualification of experts, the law's capacity to act in the face of scientific and social uncertainty, and the knowledge-producing and processing functions of legal proceedings.

This article reviews the resulting scholarship on the nature and implications of the law–science relationship. Four major strands are identified. One strand concerns the ways in which social analysts have conceptualized the interplay of these two institutions in shaping the authority structures and practices of modernity, particularly those legitimizing exercises of power in democratic societies. A second area relates to the law's impact on the emergence and professionalization of scientific and technical disciplines, especially in the social and behavioral sciences. A third focuses on responses by courts and their critics to the expanding influence of expert witnesses and associated shifts in rules governing the admissibility of expert testimony. Fourth and finally, a fast-growing stream of research looks at the law as a site for generating new scientific knowledge and technical expertise and inquires into the implications of this mode of knowledge-making for individual and social justice.

Law, Science, and the Transition to Modernity

Since the origins of modern scientific thought, the term 'law' has been used to describe both regularities discernible in nature and rules laid down by religious or secular authorities to guide human conduct. Both kinds of laws, it was once assumed, embody unchanging principles that work always and everywhere in the same fashion, even though Robert Boyle, a founder of experimental science, cautioned against a literal assimilation of the behavior of matter under natural law to the behavior of human agents under civil law (Shapin, 1994: pp. 330–331). For H.L.A. Hart, the renowned British legal theorist, certain natural facts (such as the approximate equality of humans, their vulnerability, and the limits of their resources and altruism) underwrote a 'natural law' without which human societies would not be able to retain their salient moral characteristics (Hart, 1961). Taking a more sociological tack reminiscent of Robert Merton's well-known 1942 essay on the norms of science, the American legal philosopher Lon Fuller argued that law and science resemble each other in possessing an internal morality that results from the distinctive

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86107-3

arrangements, practices, and fiduciary demands of each institution (Fuller, 1964). Later legal scholarship contrasted the 'cultures' of law and science and likewise underscored their normative and procedural particularities (Goldberg, 1994; Schuck, 1993).

Yet, historical research shows that science and law have continually drawn on each other's institutional strengths and attributes. Thus, early experimental science derived its legitimacy from enlisting the testimony of witnesses, both real and 'virtual' (Shapin and Schaffer, 1985), as if in a court of law. In reverse, some argued that science's self-regulating, nonhierarchical modes of governance offered a model or prototype for the democratic operation of society (Polanyi, 1962). The Enlightenment of the eighteenth century and the rise of liberal democracies brought science and government together in pragmatic projects to ameliorate people's lives (Price, 1985). In the United States, Thomas Jefferson drafted the first Patent Act of the fledgling American republic in 1793, giving operational effect to the constitutional provision that Congress has power "to promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries." More recently, the partnership of scientific and political authority has furthered instrumental rather than idealistic ends. Modern governments turned to science and technology to discipline citizens and to secure their assent to state rule (Foucault, 1979). State-sponsored technology programs to some degree bypassed consensus-building through deliberation, the staple mode of democratic lawmaking. Instead, states sought to establish their effectiveness through public demonstrations. In projects ranging from vaccine development to space exploration to military exploits, publics were called on to attest to the state's performance, much as scientists bore witness to each other's observations in early experimental laboratories (Ezrahi, 1990). Unlike legislation, however, the design and deployment of technologies by the state often resisted democratic supervision and control (MacKenzie, 1990; Winner, 1986).

The law's dependence on science was perhaps most transparently visible in the US, a society in which lawsuits abound and routinely pave the way to significant policy change. By the beginning of the twentieth century, ideological and political dogma favored the belief that state social policies could and should be responsive to empirical evidence from the sciences. An icon of the progressive era, U.S. Supreme Court Justice Louis D. Brandeis, pushed this development through his historic 'Brandeis brief' in *Muller v. Oregon* (1908). Written to defend Oregon's 10-hour working-day restriction on women's employment, the 100-page brief is widely regarded as the first attempt to bring social science arguments into the courts. Brandeis, then a public interest lawyer in Boston, successfully argued that women were sufficiently different from men to justify special legislative protection, thereby distinguishing the Oregon case from the Court's earlier, infamous decision in *Lochner v. New York* (1905), which struck down a similar state law curtailing working hours for male bakers.

Social science evidence received a further boost when, in overturning the 'separate but equal' doctrine that supported racial segregation in public schools, the U.S. Supreme Court in *Brown v. Board of Education* (1954) relied on psychological studies of segregation's 'detrimental effect upon the colored children.' In later years, students with disabilities benefited from similar sorts of evidence in claiming rights to special education (Minow, 1990). Employment discrimination, racial segregation, gay rights, antitrust, capital punishment, and environmental liability were among the many litigated subjects that brought floods of social science testimony, often involving new methods of counting and quantification, into the US courts through the turn of the twenty-first century. Scientific professional societies, such as the American Psychological Association and the American Sociological Association, filed *amicus curiae* (friends of the court) briefs in important appellate cases, to both assert the social value of their branches of science and their own right to declare what counts as authoritative knowledge with respect to the issues at stake. These developments kept alive the view that objective scientific information about society could be invoked in legal proceedings to combat recognized forms of oppression and social injustice.

The relationship between law and science in modern Europe was no less pervasive, though in some ways more covert than in the United States, where litigation regularly serves as politics by other means. The crises of industrialization and the rise of the welfare state created a demand for credible public action supported by science. States responded with rapid increases in their institutional capacity to order and manage society through newly accredited social science disciplines (Wagner et al., 1991). In turn, the classifications and measurement technologies offered by the human sciences provided the basis for new forms of self-understanding, normalization, and social control. Whether in medicine, psychology, criminology, or studies of intelligence (Carson, 2007), science offered criteria for dividing people into categories of normal or pathological, mainstream or deviant. The scientific study of human characteristics thus enabled members of society to see and discipline each other without the need for constant, formal regulatory oversight by the state (Foucault, 1990, 1979). Science, on this account, not only underwrote the state's formal legal authority to govern its subjects, but also replaced some of the ordering functions of positive law.

The demand for science-based decision-making created a widening sphere for expert advice to governments around the world. Studies of 'regulatory science' (Jasanoff, 1990) called attention to policy-relevant knowledge as a distinctive domain of knowledge production, different from research science in its contexts of production and application, and presenting its own problems of credibility, accountability, and quality control (Lentsch and Weingart, 2011). More, however, was at stake in the shift from science, anchored by the ideal of truth to nature, to expertise, rooted in the exercise of judgment. Nature seems to speak for itself through science; experts, in contrast, are mere humans, and therefore fallible, and they are called upon in just those situations where certainty about facts is most elusive. What, then, accounts for the law's faith in experts? At issue in investigations of regulatory science were the foundations of trust in experts' cognitive authority and the state's performances of public reason. The need for comparative, cross-cultural research on such issues became evident (Jasanoff, 2005), though research capacity, including relevant linguistic and cultural knowledge, remained in short supply.

Disciplines, Professions, and the Law

The interactivity of law and science spurred new disciplinary formations and helped change professional norms, especially in the human sciences, which serve both as putatively neutral allies in regulatory and law enforcement programs and as uneasy subjects of the law's skeptical gaze. This dual relationship between law and the social sciences – at once necessary and suspect – prompted new lines of research and theorizing, along with periodic encroachment by legal authorities upon science's professional autonomy. Developments in the fields of risk studies and psychology clearly illustrate these patterns.

The Social Sciences of Risk

The scientific study of risk grew out of state efforts to manage the hazards of industrial production, complementing modern governments' reliance on older formal decision-making tools such as cost–benefit analysis. Uncertainty about technology's risks and benefits increased through the twentieth century, along with the size and complexity of networks of production and distribution. From village-based economies, in which injured parties knew with fair certainty the causes of the harms they had suffered, the global economy pulled consumers into webs of relationships that diffused both information about risks and responsibility for regulation and compensation. Epitomizing the plight of industrialization's innocent victims, millions of asbestos workers worldwide were unknowingly exposed to severe health risks, and hundreds of thousands died of asbestos-induced illnesses. As the magnitude of such disasters became apparent, legislatures sought to enact preventive rules, ensuring that proof no longer needed to arrive in the form of 'body counts.' Risk, not harm, became the basis for action under new laws safeguarding health, safety, and the environment; and state agencies struggled to develop scientific techniques for measuring, assessing, and mitigating risks before injuries occurred on mass scales.

From relatively modest beginnings rooted largely in the engineering and physical sciences (as in calculating the risk of accidents in nuclear power plants), risk assessment to support regulatory standards grew into an important, and contested, branch of the social sciences by the end of the twentieth century. Risk studies acquired markers of professionalization, with dedicated journals, societies, curricula, and research centers at major universities. An important focus of work in this field, particularly in the United States, was the construction of reliable models for measuring the probability of harm, ranging from the use of animals as stand-ins for humans to sophisticated methods of representing uncertainty in risk estimates (National Research Council, 1994). Risk assessment presented not only methodological but also institutional challenges for governments needing to persuade industry and the public that regulatory decisions were politically balanced and scientifically sound (Jasanoff, 1990). Lawsuits questioning the risk assessment practices of US federal agencies were commonplace and led to significant judicial decisions, including Supreme Court rulings on the occupational standard for benzene in 1980, on air quality standard for particulates in 2001, and on the Environmental Protection Agency's failure to regulate greenhouse gases in 2007.

Other researchers meanwhile approached risk from the standpoint of social psychology, asking why lay observers frequently diverge from experts in judgments concerning the relative magnitude of different kinds of risk. This question produced a sizable and influential body of experimental and survey work on risk perception (Slovic, 2000), as well as theoretical critiques of such work (Irwin and Wynne, 1996). While some social scientists focused on identifying and measuring 'real' risks, and public perceptions of them, others treated *risk* itself as a new organizing principle in social life, noting that vulnerability to risk no longer maps neatly onto older divisions of society according to race, class, and economic status (Beck, 1992).

A new line of research at the intersection of economics and cognitive psychology rose in prominence and policy relevance by the turn of the century. At the base were studies showing that individuals make – from an economic standpoint – systematically irrational choices when confronted with certain kinds of judgments, including decisions about risk (Kahneman, 2011; Kahneman et al., 1982). Originally designed to contest core assumptions about human rationality in economics, these studies demonstrated that the capacity to choose rationally is often compromised by people's prior assumptions and experiences. These biases and heuristics frequently lead to overly fearful or overly optimistic assessments of loss and gain that do not correspond well to actual measured probabilities of events. Findings from the new decision sciences quickly migrated into law and policy. In particular, for government regulators seeking a politically neutral basis for governance, these findings supplied welcome grounds for the 'libertarian paternalism' of 'nudging,' that is, structuring choice frameworks so as to steer people toward making what policy specialists deemed to be the right or most rational choices (Thaler and Sunstein, 2008).

In sharp contrast to these approaches grounded in individual cognitive psychology, the US environmental justice movement generated politically persuasive, if also methodologically contested, data suggesting that social inequality still matters profoundly in the distribution of industrial risks, which fall disproportionately on poor and minority populations (Bullard, 1990). This research led in 1994 to a presidential executive order demanding that US federal agencies should consider the equity implications of their actions. More generally, social impact analysis emerged as an offshoot of existing methodologies for assessing risk, and statistically grounded claims of environmental injustice offered new grounds for demanding regulatory action.

Psychology and Law

Unlike formal risk analysis, which is largely a product of twentieth century concerns, law and the mental health disciplines have existed in close reciprocity since at least 1843, when the British House of Lords laid down the so-called M'Naghten rule for determining the responsibility of persons who try to excuse their unlawful behavior on grounds of insanity. The human sciences' claimed ability to sort people's behavior and capacities into seemingly objective, 'natural' categories, such

as insanity, served the needs of both democratic and totalitarian states in a variety of legal contexts. In US law, for example, psychiatric evidence was used to determine whether an accused criminal could stand trial, whether conditions for sentencing leniency or parole were met, and whether a criminal convicted of a heinous crime posed a sufficient threat of long-term dangerousness to deserve the death penalty. These intersections provided new professional opportunities for psychiatry and psychology, spawning a thriving pedagogic specialty of law and mental health (Gutheil and Appelbaum, 2000). Indeed, the state's need to determine people's mental states in civil as well as criminal proceedings was an important driver of professionalization in mental health fields.

Entanglements with the law, however, also revealed disagreements among psychiatric experts and undermined their disciplinary authority in other ways. A notable example occurred in the 2012 trial in Norway of the notorious mass killer Anders Breivik who had fatally bombed and shot 77 people the year before. A team of two court-appointed psychiatrists initially found him to be a paranoid schizophrenic, but a second two-person team diagnosed him as sane and suffering from serious personality disorders. The latter diagnosis meant that Breivik would serve time in prison rather than in a low security psychiatric hospital. The majority of Norwegians, and Breivik himself, agreed with the finding of sanity, but the case also showed how pliant forensic psychiatric expertise can be, especially when confronted with strong public opinion.

An early but seminal challenge to psychiatrists' professional autonomy occurred in the 1974 US case of *Tarasoff v. Regents of the University of California* (redecided in 1976). Here, the California Supreme Court ruled that psychiatrists are required to warn (later changed to have a duty to protect) third parties threatened by their patients. Although the decision did not open the floodgates to liability as therapists had feared, *Tarasoff* was widely seen as influencing therapeutic practice by making practitioners more attentive to threats posed by violent patients. In another notable decision, the U.S. Supreme Court in *Barefoot v. Estelle* (1983), a death penalty case, essentially ignored an *amicus* brief by the American Psychiatric Association (APA) stating that psychiatric predictions of dangerousness are wrong in as many as two out of three cases. The Court expressed confidence that juries would be able to evaluate such evidence even if it was weak or deficient, thereby denying privileged status to the APA's professional expertise.

By the end of the twentieth century, the alliance between law and the human sciences – joined, eventually, by genomics and powerful imaging techniques from the neurosciences (Dumit, 2004) – helped to define a host of novel disorders and syndromes invoked to extenuate or penalize various types of conduct. Posttraumatic stress disorder (PTSD), for example, along with its specific manifestations such as rape trauma syndrome, entered the DSM-IV, the official diagnostic handbook for psychologists, in spite of scholarly doubts that PTSD is a scientifically discoverable, universal phenomenon (Young, 1995). Codified in DSM-IV, PTSD became not only an identifiable and presumably treatable medical condition, but also a basis for asserting new legal claims (as in lawsuits for stress-related psychological injury in the workplace), or defending oneself against charges (as in murder trials of sexually abused defendants).

A notorious synergy between law and psychology occurred in a rash of so-called recovered memory and child abuse cases, which gained prominence in the United States in the 1980s (Hacking, 1995). Psychiatrists and psychologists testified as experts, initially to the reliability of recovered childhood memories, but these cases caused scandal as witnesses later recanted and it became apparent that some experts had more likely instilled than elicited the shocking 'memories.' The profession eventually organized to deny the scientific validity of the claims and the expertise of the claimants (Loftus and Ketcham, 1994).

Research on eyewitness identification, another branch of science dealing with memory and recall, also received its chief impetus from the legal process and remained in constant dialogue with the law (Wells and Quinlivan, 2009). Troubled by high error rates on the part of eyewitnesses, psychologists tested people's ability to recognize persons they had encountered in stressful situations and discovered that many factors, such as race, inhibit accurate identification under these circumstances (Wells, 1988). Hundreds of studies with similar findings began to have an impact on police procedure by the late 1990s, as awareness dawned that relatively simple changes, such as sequential rather than simultaneous presentation of suspects in line-ups, could substantially improve the reliability of eyewitness testimony. Nonetheless, in 2012 the U.S. Supreme Court ruled that, in the absence of police misconduct, the introduction of eyewitness testimony without prior judicial scrutiny was not a violation of due process.

Scientific Evidence and Expert Witnesses

The civil law system relegated the production of scientific and technical evidence largely to court-appointed experts, thereby short-circuiting public conflicts between experts. Common law proceedings by contrast traditionally left it to the parties themselves to produce evidentiary support for their claims, with disputes resolved through questioning in pretrial and courtroom contexts. The adversary process, with its ritual of cross-examination, was assumed to be equal to the task of testing the evidence, no matter how arcane or technical, thereby permitting the fact-finder – the judge or the jury – to discern the truth. Although commentators often deplored the practice of treating experts as hired guns, the parties' right to present their own evidence was not in doubt, and courts rarely used their acknowledged power to appoint independent experts who might offer a more disinterested view (Jasanoff, 1995).

By the turn of the century, several social transformations pressured judges into taking a more proactive stance in relation to expert witnesses. The sheer volume of cases demanding some degree of technical analysis was one key factor, especially in the US, where low entry barriers to litigation and the inadequacy of social safety nets routinely brought to the courts controversies that were resolved by other means in most common law jurisdictions. Highly public instances of expertise gone awry, as in the recovered memory cases, shook people's confidence in the power of cross-examination to expose charlatans posing as scientists. The economic consequences of successful products liability lawsuits strained the system from

another direction, especially in a growing number of mass tort actions that threatened entire industries with bankruptcy. It was tempting to blame these developments on the epistemic shortcomings of the adversary system: the passivity and low scientific training of judges, the technical illiteracy of juries, the gamesmanship of lawyers, and the bias or incompetence of experts selected by parties. These perceived deficits led to calls for reforming the process for admitting expert testimony into the courtroom.

Early critique reflected a turn away from the liberal ideals of the 1970s. In an era of governmental retrenchment and economic conservatism, the attack on courtroom science proved to be politically powerful, though it was neither methodologically rigorous nor of lasting scholarly value. One influential broadside accused courts of deciding cases on the basis of 'junk science,' a rhetorically useful label that took hold with opponents of the burgeoning tort system though it proved difficult to characterize systematically (Huber, 1991). The barely concealed purpose of this and related writings was to remove the testing of scientific evidence as much as possible from the adversary system, particularly from jury deliberations, and to decide admissibility issues either in pretrial proceedings conducted by judges or with the aid of scientists appointed directly by the courts. This literature displayed an abiding faith in science's self-corrective ability and a technocratic conviction that truth would eventually win out if only the legal system left scientific fact-finding to scientists (Foster and Huber, 1997). These attacks also turned the clock back in a sense, toward the older presumption that, on any contested issue, mainstream expert opinion exists independently of the legal process and can be validated with unambiguous tests of 'good' and 'bad' science. These positions were eventually thrown into doubt, but not until their polemical force had left a substantial mark on American scientific and legal thought.

Studies by practicing scientists, physicians and some legal academics converged on the theme of the law's misuse of science. Critics cited tort cases in which multimillion dollar jury verdicts favorable to plaintiffs conflicted with the opinions of respected scientists who denied any causal connection between the alleged harmful agent, such as a drug or workplace toxin, and the harm suffered. Particularly noteworthy was the litigation involving Bendectin, a medication prescribed to pregnant women for morning sickness and later suspected of causing birth defects in their children. Juries frequently awarded damages despite repeated assertions by epidemiologists that there was no statistically significant evidence that Bendectin was responsible for the claimed injuries. Sociological research showed suggestive differences in behavior (such as discrepant rates of repeat witnessing) between experts for plaintiffs and for defendants (Sanders, 1998), leading some to question whether offers of scientific testimony were being adequately screened. Another case that drew considerable critical commentary was litigation involving silicone gel breast implants. Close to a half-million women surgically implanted with these devices sued the manufacturer, Dow Corning, claiming injuries ranging from minor discomfort to permanent immune system damage. The company's initial settlement offer broke down under a torrent of legal action, but epidemiological studies, undertaken only after the commencement of lawsuits, showed no causal connection between the implants and immune system disorders. Publication of these results in the prominent *New England Journal of Medicine* led its executive editor to join the chorus of accusation against the legal system's apparent disregard for sound science (Angell, 1996).

Rising discontent about the quality of scientific evidence led the US Supreme Court to address this issue for the first time in 1993. In *Daubert vs Merrell Dow Pharmaceuticals*, the Court set aside the so-called *Frye* rule that had governed the admissibility of expert testimony in federal courts for the preceding 70 years. Instead of simply demanding, as *Frye* had, that scientific evidence be 'generally accepted' within the relevant peer community, the Court urged judges to screen science in accordance with standards that would be used by scientists themselves. As examples, the Court offered four criteria: (1) was the evidence based on a testable theory or technique, and had it been tested; (2) had it been peer reviewed; (3) did it have a known error rate; and, recapitulating the older admissibility rule, (4) was the underlying science generally accepted? Two more major evidence decisions of the 1990s cemented the high court's message that trial judges should play a vastly more proactive and independent gatekeeping role when confronted with scientific and technical evidence. As judicial involvement in admissibility decisions increased, new complaints appeared on the horizon: that judges were inappropriately using the *Daubert* criteria as an inflexible checklist rather than as the guidelines they were meant to be; that mechanical application of *Daubert* and its progeny was trumping deserving claims; that judges were usurping the jury's constitutional role; and that misinterpretation of *Daubert* was introducing unscientific biases and impermissibly raising the burden of proof in civil cases.

In most civil law jurisdictions, by contrast, the inquisitorial approach to testing evidence, coupled with the state's near monopoly in generating forensic science, precluded similar controversy about the legitimacy of experts or the quality of their testimony. As US courts moved to consolidate their gatekeeping function in the 1990s, constricting the entry routes for experts, a countermove of sorts could be discerned in a few European legal systems to open the courtroom door to a wider diversity of expert opinion (Van Kampen, 1998).

Law as a Site of Knowledge-Making

Investigation of the law–science relationship took a more sophisticated turn in the 1990s as it attracted the attention of a new generation of researchers in science and technology studies. From this disciplinary vantage point, the use-misuse framing that had dominated popular writing appeared superficial, especially when set against the observable richness of social interactions between the two institutions. Rather, as this body of work sought to demonstrate, it was the hybridization of law and science that held greatest interest and significance for both science and society. At this live frontier of social problem-solving, one could observe in fine-grained detail how important normative and epistemological commitments either reinforce or contradict each other in contemporary societies. For example, even within the common law's adversarial environment, the ritualistic character of legal proceedings successfully holds the line

against certain forms of radical skepticism, leaving untouched traditional hierarchies of expert authority (Wynne, 1982), belief in the ultimate accessibility of the truth (Smith and Wynne, 1989), and an abiding faith in technological progress (Jasanoff, 1995).

At the same time, the legal process came to be recognized as a distinctive site for the production of socially significant yet otherwise unavailable knowledge and expertise. Even in cases where litigation arguably produced anomalous results – such as those involving Bendectin and breast implants – resort to the courts added to society's aggregate store of information. In these and countless other cases, plaintiffs' claims spurred inquiry into social phenomena that no one had previously thought to study; litigation-driven scientific knowledge was produced under conditions of methodological instability and potential bias, but was relevant nonetheless for righting old wrongs and protecting against future risks. Corporate resources too played an increasing role in the production, and the nonproduction (Proctor and Schiebinger, 2008), of knowledge relevant to policy and social justice. In numerous cases, corporate funding sought to destabilize relatively secure, peer reviewed science supportive of regulation by commissioning studies to raise doubts about the prevalent consensus (Michaels, 2008). All these efforts can be seen as part of the broad sociological shift in knowledge production away from ivory tower science toward ends-oriented research in the later twentieth century (Gibbons et al., 1994).

Other cases of law-driven knowledge production seemed unambiguously progressive. A noteworthy example was the importation of molecular biological techniques into the domains of criminal identification and paternity testing in the form of 'DNA typing.' Legal needs for better identifiers provided the initial context for the technique's move from the laboratory into forensic settings (Aronson, 2007). Subsequent contestation over the reliability of DNA-based identification among ethnic sub-populations had impacts on the field of population genetics and spurred the formation of new testing methods and agencies, as well as the standardization of commonly used tests (Lynch et al., 2008; Lynch and Jasanoff, 1998). As the technique became black-boxed, new market niches for it emerged within the legal system, most spectacularly in the formation of the US-based Innocence Project, a legal collective dedicated to exonerating mistakenly convicted persons. The success of DNA as a forensic tool also helped to destabilize the legal system's longstanding commitment to eyewitness evidence, thereby providing for research critical of the ancient privileging of visual memory (Wells, 1988). But the massive uptake of forensic DNA analysis by the criminal justice system also opened up new areas of social concern, such as privacy and database protection (Hindmarsh and Prainsack, 2010), not to mention outright misconduct, which called for continued vigilance and ingenuity on the part of the legal system (Jasanoff, 2011).

The injection of molecular biology created unexpected ripple effects for other branches of forensic science. Here finally was a domain of law enforcement that seemed firmly grounded in knowledge of nature as opposed to the say-so of potentially biased human experts whose job was to facilitate prosecutions. Fresh skepticism challenged even that most black-boxed tool of the criminal justice system, fingerprinting, revealing weaknesses in its validation and inconsistencies in its use (Cole, 2001). Just as regulatory science had emerged as a field of contestation in the last quarter of the twentieth century, so forensic science took center stage as a new arena for controversy and demand for reforms in the 21st. In 2009, the influential U.S. National Academy of Sciences called for the formation of a new institute to oversee training, accreditation, and research in forensic science, though implementation in a time of financial austerity looked unrealistic.

The rise of DNA typing, like that of risk analysis and PTSD, reflected the dynamics of an epoch in which the establishment of any form of social order became virtually unthinkable without the mutual engagement, or coproduction, of law and science. In such a time, commentary deploring the law's alleged misuses of science appeared increasingly simplistic and out of touch with the everyday reality of deep interpenetration between the two institutions. The emergence of science and law as a special topic within the social sciences, especially in science and technology studies, responded to the inadequacies of earlier analyses premised on reductionist assumptions about science, law, and their interactions. A major contribution of this work was to discredit once for all the pared down 'clashing cultures' model of the law–science relationship and to put in its place a more nuanced picture of the interplay between epistemic and normative authority. By exploring in detail how the law not only 'uses' and 'misuses' science, but also generates it, questions it, assesses science-based technologies, and often compensates for their inadequacies, the new scholarship on science and law invited reflection on the intricate balance of truth and justice in technologically advanced societies.

Abstract

Although science and media have long been perceived as separate realms, recent scholarship has highlighted their mutual dependence. Media play a fundamental role in the creation of scientific knowledge, and at the same time provide a forum in which public debate about science shapes the social matrix in which scientific institutions operate. Scholars have identified a complex web of interaction among different scientific activities and different media with different audiences. Current research in the field explores political and economic interests of science media producers, rhetorical conventions of scientific presentations, and audience responses to science information.

The phrase 'science and the media' as a single concept encompasses two major social institutions. Science is both a system of reliable knowledge about the natural world and a complex social system for developing and maintaining that knowledge. Similarly, the media comprise a variegated system for collecting and presenting information as well as being an institution with significant economic, political, and social impact. Though long perceived as separate realms, recent scholarship has highlighted their mutual dependence. Increasing episodes of tension and conflict in the late twentieth century led scholars, scientists, media producers, and social critics to explore the interactions of science and the media. Working scientists and media producers sought guidance on how to use each others' resources more effectively, while analysts asked how such issues as political and economic interests, rhetorical conventions, and audience responses shed light on the roles of science and media in shaping each other. One effect of recent scholarship has been to elide the difference between 'media' (all forms of media) and 'the media' (particularly the major institutions of newspapers, magazines, television, and radio), an elision that will be evident throughout this article.

Science and the Media: A Brief History

The history of science and the media is the history of a growing mesh: increasing use of media by science, increasing attention to scientific ideas by media institutions, and increasing tensions caused by the rising interaction.

Through the middle of the twentieth century, science and media were largely seen as separate realms. Science had emerged in the nineteenth century from natural philosophy as a systematic approach to understanding the natural world. With the advent of research-based industries such as chemical dyes and electronic communication, science began to attract the attention of capitalists and government leaders who understood the value of controlling scientific knowledge. By the end of World War II, the emergence of 'big science' had made science a powerful institutional force as well as a system of accredited knowledge with increasingly far-reaching applications. The media had also evolved in the nineteenth century from small, local organizations into nationally and internationally circulated publications that served as tools of merchant capitalism and political control, full of advertising, business and political news, and the ideology of the industrial revolution. By the early twentieth century, new electronic media such as movies and radio provided the means for newly developed forms of 'publicity' and propaganda to help produce modern mass society, as well as to increase public access to new forms of cultural entertainment.

Since the late seventeenth century, natural philosophers had relied on print media, particularly professional journals such as the *Philosophical Transactions* and books such as Isaac Newton's *Principia*, as tools for disseminating the results of their investigations. These publications were not only records of experiments or philosophical investigations, but also served as active carriers of the rhetorical structures that enabled natural philosophers to convince people outside their immediate vicinity of the truth of their claims (Shapin and Schaffer, 1985).

Early in the nineteenth century, new forms of science media emerged, particularly a genre known variously as 'popularization,' *vulgarisation* (French), or *divulgacion* (Spanish). These books and magazines provided entrée into the knowledge of the natural world for non-scientist readers. They ranged from textbooks for young women through to new mass-circulation magazines filled with instruction on the latest achievements of a rapidly industrializing society. The so-called 'great men' of late nineteenth-century England (most notably Thomas Huxley and John Tyndall) became evangelists for science, lecturing widely to enlist public support for the enterprise of rational understanding of the natural world; they converted their lectures into articles and books to spread their reach even further. At the same time, scientists' use of media for disseminating knowledge among the scientific community grew dramatically, with the growth of new journals and the founding of publishing houses committed to scientific information.

The growth of both science and media in the twentieth century forced specialization into the fields, leading to a distinction between what some scientists have called 'communication in science' and 'communication about science.' For scientists in their daily work, broad synthetic journals such as *Science* and *Nature* (published respectively in

the USA and the UK) were joined by topical journals in chemistry, physics, biology, and their many sub-disciplines. For non-scientists, magazines and other media (such as radio and new 'wire services' for newspapers) increasingly focused on particular audiences, such as teachers, inventors, 'high culture' readers, general media users, and so on. Although scientific ideas appeared in some entertainment media, science in most non-technical media became a component of news coverage for different audiences. In the 1920s and 1930s, a small group of professional journalists began to write almost exclusively about science. (These developments were clearest in the highly developed countries of Europe and North America. The patterns in the rest of the world have been little studied and so cannot be described.)

By the second half of the twentieth century, the interaction of science and media had become a complex web, in which new scientific research appeared in abstracts, journals, press reports, and online, while other forms of science – not necessarily derivative of the research reports – appeared regularly in media outlets such as newspapers, televisions, websites, radio programs, puppet shows, traveling circuses, and museums. Moreover, as science became central to modern culture, the presence of science in media such as poetry, sculpture, fine art, entertainment films, and so on, became more evident. In the journalistic media, many reports circulated internationally, through cooperative agreements between public broadcasting systems and worldwide news services. The rise of the World Wide Web in the 1990s provided further opportunities for information about science to circulate more fully between the developed and developing world.

However, from about the mid-century onward, no matter what media were involved, many working scientists perceived presentations in non-technical media to be incorrect, oversimplified, or sensationalized. Thus, tensions developed between the institutions of science and those of the media. Those tensions led eventually to the development of an analytic field of science and media, populated largely by media sociologists, communication content scholars, and sociologists of science.

Understanding Science and Media

Analysis of science and media has led to a deeper understanding of the essential role of media in creating scientific knowledge, the ways that media presentations shape understandings of nature, and the role of public debate in constituting scientific issues.

The earliest attempts to understand the relationship of science and media came from two directions: the overwhelming growth of scientific information, leading to attempts by scientists and scientific institutions to learn how to manage scientific publications, and emerging tensions between scientists and journalists, as specialized reporting developed in the 1930s. Research and publications before and after World War II led by the 1970s to two common understandings.

First, sociologists of science had come to understand the fundamental role of communication in the production of reliable knowledge about the natural world. Scientists do not work in isolation, but must constantly present their ideas to colleagues for acknowledgement, testing, modification, and approbation. The process of communication, occurring in various media, is the 'essence of science' (Garvey, 1979), leading to science becoming 'public knowledge' (Ziman, 1968). At the same time, the apparent differences between the goals of science (methodical, tentative, but nonetheless relatively certain statements about the natural world) and the needs of public media (rapid, attention-getting narratives about issues directly related to readers and viewers, regardless of certainty) had also been explicated (Krieghbaum, 1967), leading to practical attempts to 'bridge the gap' between science and the media but also to recurring fears that the gap was unbridgeable.

Beginning in the 1970s, new developments in the sociology of scientific knowledge opened up new ways of conceiving of the relationship between science and media (Barnes, 1974; Latour and Woolgar, 1979). In particular, attention to the rhetorical goals of scientists in their use of media suggested that a distinction between communication in science and communication about science could not be maintained. Instead, some researchers began to discuss the 'expository' nature of science, showing how scientists tailored their communication to meet the needs of specific media and specific communication contexts (Bazerman, 1988; Shinn and Whitley, 1985). These researchers highlighted the interaction of the idealized intellectual goals of science (for the production of reliable knowledge about the natural world) with the social and institutional goals of scientists and their employers or patrons (for priority, status in the community, ownership of ideas and thus patents, and so on).

In this conception of science and media, scientific knowledge itself might differ in different presentations – in some cases, appearing as a 'narrative of science' (focusing on the methodological and theoretical structures leading to particular knowledge of the natural world), in other cases as a 'narrative of nature' (focusing on the relationships between organisms or entities, with emphasis on the 'story' linking different aspects of those organisms and entities) (Myers, 1990). The very boundary between 'science' and 'non-science' (or 'mere' popularization), between communication in science and communication about science, was shown to be highly mutable, itself an object of rhetorical construction used for political purposes by participants in scientific controversies to establish control over elements of a debate (Hilgartner, 1990).

A second new line of inquiry highlighted the institutional interdependence of science and the media. Pointing to the growing post-World War II need for scientific institutions to generate public and political support, and to the media's need to draw on scientific developments for constant infusions of drama and 'newness,' the new research identified 'selling science' as a major element of the political economy linking science and the media (Nelkin, 1987).

Finally, work on the images of science that appeared over time helped show the ways that social concerns interacted with scientific developments to create cultural representations of science (Weart, 1988; LaFollette, 1990; Nelkin and Lindee, 1995).

At the same time that these developments were occurring in the understanding of science communication, new approaches were developing in understanding the relationship between science and the public. Spurred by concerns in the scientific community about lack of 'scientific literacy,' the studies ultimately questioned the idea that the public has a 'deficit' of knowledge that needs to be 'improved' (Irwin and Wynne, 1996). Instead, the new approach focused on the possibility of engaging the public in discussions about scientific issues, recognizing the contingent nature of understanding of scientific issues and thus the alternative meanings that might emerge in democratic discussions instead of authoritarian pronouncements (Sclove, 1995). Much of the new work looked at issues of uncertainty and risk, highlighting the social negotiations required to make personal and policy decisions in a context of incomplete information (Friedman et al., 1999). The new work clearly implied that science and the media cannot be perceived as separate institutions with separate goals. Instead, better understanding comes from analyzing science and media across audiences, looking at the political and economic interests of media producers, at the rhetorical meanings of media conventions, and at the audience responses to media content (especially in terms of meaning-making).

Approaches to Studying Science and Media

Political and Economic Interests of Media Producers

The most detailed and well-developed understandings of science and the media point to the political and economic interests that motivate the producers of media representations of science. In many countries, the media depend on government subsidies or at least on political tolerance. Moreover, media are expensive to produce. While the presence of the media in democratic societies is often seen as fundamental to political liberty, the economic need to appeal to broad audiences (even for government-controlled media) often leads to editorial decisions that emphasize broad coverage and sensationalism over depth and sobriety. Science media are no different, and even the most prestigious scientific journals such as *Science* and *Nature* have been criticized for highlighting the most 'newsworthy' research, for hyping scientific reports beyond their value, for engaging in 'selling science.' Newspaper and television coverage of science is routinely criticized for its sensationalism, particularly in the coverage of controversial issues such as food contamination (e.g., the BSE or 'mad cow' epidemic in Britain in the 1980s and 1990s), genetic modification of food, and global climate change. Journalists (and their employers) routinely defend their practices on the basis of 'what readers/viewers want,' which is often judged by sales success. Entertainment media are criticized even more heavily for creating movie plots that involve impossible science or focus on highly unlikely scenarios; producers disclaim any responsibility for accuracy, claiming only to be providing (profitable) escapism. These recurring disputes between the scientific community and media producers highlight the irreconcilable tension between the goals of science and the goals of the media.

Rhetorical Meanings of Media Conventions

An emerging area of understanding is the way that media conventions shape the rhetorical meaning of science communication. Scientific papers reporting original experimental research, for example, have developed a standardized format (called 'IMRAD,' for introduction, methods, results, analysis, discussion). The IMRAD format, conventionally written in an impersonal tone, with passive grammatical constructions, hides the presence of the researcher in the research, highlighting the objective character of scientific knowledge that is claimed to exist independently of its observer. In journalistic reports of scientific controversies, the conventions of objective reporting require 'balance' – the presentation of both sides of a controversy (Bazerman, 1988). Though 99.9% of all researchers may hold that a new claim (such as the eventually discredited 1989 announcement of a new form of 'cold nuclear fusion') is scientifically untenable, the journalistic norm of balance may lead to approximately equal attention to all claims. Similarly, journalistic goals of story telling often lead to emphasis on the human, narrative dimensions of an issue over the theoretical or mathematical components of the science. New research is exploring the meaning of visual representations of science, at every level from the technical outputs of genome analyzers to mass media manipulations of false-color images produced by orbiting astronomical telescopes (Lynch and Woolgar, 1990).

Audience Responses to Media Content

One of the most difficult areas to investigate is the audience response to particular media presentations. Virtually no work, for example, has been done on how scientists respond to specialized science media, despite anecdotal stories suggesting that changes in information presentation (such as World Wide Web access to scientific databases) may have dramatic impacts on how scientists conceive of the natural world and frame their hypotheses and theories. Some work has been done at broader public levels, such as responses to media presentations of risk information. But, although the psychology of risk perceptions, for example, has been extensively investigated, the factors affecting individual responses to media coverage of specific risky incidents are so varied as to defy measurement. Though the complexity leads some researchers to reject the possibility of quantitative analysis, others insist that social scientists can learn to isolate appropriate variables. Certainly some areas of audience response could be investigated more carefully; audience reaction to images of science in entertainment films, for example, has never been systematically tested, despite frequent statements that 'the image of scientists in the movies is bad.'

The shift away from separate analysis of 'science' and 'media' to an integrated understanding of 'science and media' has led in recent years to the possibility of cross-cutting analyses, such as those of producers, rhetorical structures, and audience reception. These analyses will ultimately yield a much richer understanding of the interaction of science and media. Less clear is how such improved understanding will contribute to the practical concerns of those in the scientific community and elsewhere, who worry about possible linkages among science literacy, the image of science, and public support for science.

Science and Politics: Value Neutrality

Sven Eliaeson, Uppsala centre for Russian and Eurasian at Uppsala University, Uppsala; and Centre for Social Studies, Instiute for Philosophy and Sociology at the Polish Academy of Science, Warsaw

Abstract

Science and politics is a theme where past and present meet and is hard to ignore, in particular in social science, where the research frontier is split and there are intervening vested interests; uncontrolled value intrusion is a recurrent phenomenon. Max Weber's views on value neutrality and the relation between value neutral knowledge production and political passion are popularized in his 'twin-lectures'. Myrdal, under the influence of Hägerström's value-nihilism provides a pragmatic way out of the value-incommensurability predicament, by the use of significant and relevant explicit value premises, as points of departure for social engineering. Merton codifies the ethos of unbiased science. The autonomy of research is under siege from increasing commodification, bureaucratization, and ideologization. Even if recurrently challenged, Weber's decisionism remains the standard position.

Economic notions of various origins are challenging the traditional, academic value-orientation. The ideas of unconditional truth-seeking and an institutional method of securing scientific quality are being contested. The institutionalized norm system for the pursuit of scholarship nurtures countercultures.

Science and Politics in Social Science

The topic of science and politics confronts us with a chicken-and-egg problem. Machiavellian and Hobbesian statecraft are cases in point. Civil society discourse in Scottish Enlightenment, and Samuel Pufendorf (1632–94) as an 'early bird', could be included as well. Nineteenth-century scholars such as Herbert Spencer (1820–1903) and Karl Marx (1818–83) did not make a difference between scholarship and politics. Throughout the nineteenth century, history writing served state interest and nation building, and not only in Germany. In the German case 'system Althoff' (Friedrich Althoff (1839–1908) was *Universitetsreferent* in the Prussian department of culture and managed to launch more than 140 new institutes, seminars, and clinics.) was very successful a century ago and its aim was not only to promote science but also to strengthen Prussia as a great power. Germany was at the cutting edge and Germans received many early Nobel prizes, not only in medicine and physics; Theodor Mommsen got the literature prize in 1902.

However, it was in the *Werturteilsstreit* within the *Verein für Sozialpolitik* (Social Policy Association) that the issue became imminent and Max Weber (1864–1920) left the room slamming the door in anger (see Nau, 1996).

It is reasonable to focus on the second wave of post-Enlightenment social science and take Weber and his 'twin-lectures' as points of departure. *Politik als Beruf* (The Profession and Vocation of Politics) is not a scholarly text but a popular lecture delivered in front of students at a tumultuous time in Munich's history. *Wissenschaft als Beruf* (Science as a Calling) was delivered earlier, in November 1917, when an end to World War I was still in the future.

Bavaria for a while became a Soviet republic *(Räterepublik)* with escalating violence.

With momentous events expected outside the window, the students wanted political guidance rather than the dry, taxonomical typologization which Weber had to offer.

The Weberian paradox extracted out of these lectures means that we, in our capacity as scholars, have to adhere to value-rationality and the ethics of conviction *(Gesinnungsethik)* in order to promote instrumental means–end rationality *(Zweckrationalität)* and the ethics of responsibility/consequences, which we expect from political decision makers. The scholar buys his freedom at the price of his influence in political decision-making. Alternatives could be, for instance, a technocratic order, with rule by experts.

A politician who is totally value-rational and unwilling to compromise is like a motorist driving against the traffic on the autobahn. Value-rational *Café literati* are anathema for Weber.

The Christian does what is right and places the outcome in God's hands, Weber wrote (Weber, 1994 [1919], p. 359), while the democratically elected politician is accountable and has to answer for the consequences. This division of labor between science and politics is sometimes labeled 'decisionism', a term also associated with Carl Schmitt (about Schmitt's significance in the junction of scholarship and politics, see Turner, 1999).

The background to Weber's methodological essays is a couple of intertwined controversies, *Methodenstreit* between positivism and antipositivism being the central one, but also a debate on the antipositivist side about the best way to protect the human sciences from being invaded by unified science ideals.

Despite actually siding with Wilhelm Dilthey (1833–1911) on the issue of demarcation between the cultural and natural sciences – the object and not the method being the divide – Weber makes use of the neo-Kantian philosopher Heinrich Rickert (1863–1936) in order to accomplish objectivity and intersubjectivity. There are problems of interpretation here. That Weber refers to and depends on Rickert – 'the father of historical relativism' – is explicit. The difference between Rickert and Weber remains a matter of dispute.

Rickert is a case of incoherent 'backdoor-normativism', since he claims the validity of some supra-historical, eternal generally, and unconditionally valid 'true' values. Weber does not agree, but his combined stance of distancing himself from Rickert while also defending Rickert, is not crystal clear either.

Historicism promotes historical relativism and contributes to the erosion and demise of natural law doctrines. Weber's

neighbor and friend, the theologian Ernst Troeltsch (1865–1923) discusses this in terms of polytheism in post-Enlightenment, as the problem of historicism.

Weber's 'Objectivity' essay from 1904 has a strategic place in intellectual history and was explicitly written in the aftermath of the huge *Methodenstreit* between Gustav von Schmoller (1838–1917) and Carl Menger (1840–1921), representing history versus theory. Schmoller was the dominant figure in the younger historical school and also in the founding generation of *Verein*. Historicism was hegemonic and almost all German scholars, including Weber, were 'historicists'. Carl Menger from Vienna brought British-style 'Marginalist' political economy into the German cultural sphere:

> That this problem (of objectivity, my remark, SE) is genuine and not just the fruit of empty speculation on our part, will be apparent to anyone who observes the conflict about methods, 'basic concepts', and presuppositions; the constant shift in 'viewpoints'; and the continual redefinition of the 'concepts' employed, and recognizes that the theoretical and the historical approaches are still separated from each other by an apparently unbridgeable gulf: "*two* sciences of economics!" as a despairing examinee in Vienna once sorrowfully complained. What does 'objectivity' mean in this context? *That* is the only question that will be addressed in the following discussion.
> (Weber, 2012 [1904], p. 108).

Most of the 'Objectivity' essay is dedicated to responding to the problem of the despairing student in Vienna. 'The Meaning of Ethical Neutrality', an essay from 1917 is, however, even more illustrative to the crisis of historicism as the backdrop of Weber's methodological endeavor.

Values are assigned the pivotal role in a selection process from the vast reality in which concept formation is transparent and models testable (*nachvollziehbar*), precisely what the younger historical school (von Schmoller) had difficulties to accomplish.

In the *Methodenstreit*, the political dimension was not exactly hidden. The confrontation was between the exact science and real science, abstractions versus *Wirklichkeitswissenschaft* – "as we would like to pursue it", Weber adds, in order to both mark his belonging to, and ambition to renew historicism. Persuasive and derogatory definitions were in use. British 'Robinsonaden' (rational actor model, individual rationality) were anemic and lacking in *Gestalt*. Germany was still in a process of delayed nation building in which historicism had a defining role – identity provided by the historic past, origin – and the Germans had a big brother complex against the British.

In the controversy over method, the members of the younger historical school had lowered their guard by debating how to establish laws. This made them very vulnerable since they had methodological feet of clay, where the Austrian marginalists had clear models allowing for deductions; in contrast to the mysterious nontransparent 'virgin birth' of *Realfaktoren* contributing to events; the historicist inclination was to collect data and give *Gestalt*, rather than search for *Gesetz;* they were idiographic rather than nomothetic, to use Wilhelm Windelband's terminology.

Historicism has a dual role. It is part of a German, Romantic, anti-Enlightenment trend. Yet, despite its idealist and romanticist background, as part of *deutscher Sonderweg* (A problematic concept, since it seems to assume a nomothetic notion, of a normal route; possibly *Sonderbedingungen* would have been better terminology.) and late nation-building in the search for roots, historicism also contributed to the advancement of scientific techniques and brought about both a new technical awareness, a 'feeling' for the actual material that historical research works with, and a more developed source-criticism. However, an important trademark of historicism was its animosity toward abstract concepts. Historicists felt that reality was either revealed through empirical research or grasped by some sort of empathetic or intuitive act of understanding: either way one could embrace the essence of the phenomenon under study.

Opaque practices in concept formation give leeway to uncontrolled value intrusion. This is notorious in the pre-neo-Kantian historicist tradition, as in the case of Hegel and his independent conceptual reality; while neo-Kantian nominalism enables concept-formation in a lucid way (Lepsius, 1977). Concepts are artifacts, but for historicists such as Hegel, the conceptual world is independent of us and the real one, although we might catch a glimpse of it only occasionally, e.g., Napoleon as an incarnation of the *Weltgeist*.

Weber had "two souls dwelling in his bosom" and politics was his "secret love". He was pioneering policy studies, trying to define the national interest in studies of agrarian economic trends East of the Elbe, in about 800 pages during the 1890s (sponsored by *Verein)*, with a condensed version in Weber's inaugural speech *(Der Nationalstaat und die Volkswirtschaftspolitik*, 'Freiburger Antrittsrede', 1895); (see Agevall, 2004 and Aldenhoff, 1991). Nation – more specifically the German nation as carrier of culture – was an ultimate top value to Weber.

On the crucial topic of neo-Kantian nominalism as a remedy against Hegelian essentialism and conceptual realism, see, for instance, Ralf Dahrendorf (1987, p. 574) with his strong statement that Weber's methodology is far from one-dimensional, nevertheless "above all, non-Hegelian". The same point is made by Bjarne Jacobsen (1998). It is also documented in Weber's famous statement that there are two ways to proceed: "Hegel's way or *our* way". (Documented in Bruun (2007) [1972]: 39n, letter to von Eulenburg on 11 May 1909).

What objective science can accomplish is the rationalization of value-hierarchies, at the service of means-end-rational policy decisions. The problem of norm-sender and incommensurability of ultimate 'top-values' is not solved by Weber. Weber's 'Wahlrecht und Demokratie in Deutschland' (Suffrage and Democracy in Germany) from 1917 is a telling text, possibly the best one to search for a key to Weber's own value hierarchy. He is a functional democrat or a *Vernunftsdemokrat*, just like Alexis de Tocqueville (1805–59). The soldiers returning from the trenches of World War 1 deserve a stake in the running of the government, after the collapse of the Prussian Empire. Weber is free from any illusions about the "true will of the people."

The predicament of anxiety of choice is still with us and even accentuated in post-Modernity. Evaluative judgments cannot be verified or refuted by the means afforded by any science, as Weber writes, soon after endorsing absolute polytheism as the only appropriate metaphysics and characterizing the alternatives between values as an irreconcilable

death-struggle, like that between 'God' and the 'Devil'. Weber in a suggestive manner describes the existentialist dilemma of the post-Enlightenment 'polytheist' predicament of value incommensurability. The last paragraph in 'Zwischen Zwei Gesetzen' (Between Two Laws) is very telling, where with reference to J.S. Mill, Weber characterizes the struggle between multiple and contradictory sets of values from which the scholar "has to choose which of these gods he will and should serve, or when he should serve the one and when the other" (Weber, 1994 [1916], p. 78f).

Robert K. Merton's (1910–2003) pioneering efforts (1949 [1938]) in the sociology of knowledge is a Weberian extension. Merton sees an affinity between Puritan virtues, liberal democracy and experimental research, and innovations.

Merton's CUDOS (an acronym for communalism, universalism, disinterestedness, originality and skepticism) first formulated in 1942, defines the ethos of uncompromising scholarship and is still ever-fresh, although for natural reasons questioned in the recent era of exaggerated commodification. Merton's norms apply to basic research, while applied research has a different logic. Policy research and public choice are naturally problem-orientated, just like medicine and engineering. It is no surprise that peace research promotes peace, and social science today deals with matters of environmentalism, climate change, and risk evaluation.

The Nazi government violated the 'Mertonian' ethos of science in a self-punishing way, which resulted in a mass *diaspora* of scholars from, in particular, Frankfurt am Main, with an energizing effect in American social science, where migrants play a significant role.

Edward Shils (1911–95) was engaged in the Cold Culture Wars of the Congress for Cultural Freedom (Berghahn, 2001) and monitored external threats to the autonomy of scholarship in his journal 'Minerva: A Review of Science, Learning and Policy', which he founded in the early 1960s and himself edited until his death. The 'End of Ideology' theme, engaging also S.M. Lipset (1922–2006) and Daniel Bell (1919–2011), is a good example of duality, academic freedom, and politics intertwined, 'separate but equal'.

Both Merton and Shils are – and see themselves – as extensions of Max Weber. We could here of course add Talcott Parsons (1902–79) with his focus on value-orientation combined with political commitments, for instance, concerning democratic political education in post-World War II Germany (Gerhardt, 2011).

Hans Kelsen (1881–1973) carries straws to the same stack, in his contribution to the American Political Science Review in the early 1950s (Kelsen, 1951).

In general, the narrative of scholars as politicians is a short one and not exactly a success story, except, arguably, for Thomas Masaryk (1850–1937). Historians (e.g., Adolphe Thiers (1797–1877, President of France 1871–73) were more prominent as statesmen in the nineteenth-century era of nation-building. We, perhaps, are wise to apply historical relativism, since in Europe, East of the Elbe, after the implosion of the Soviet Empire, intellectuals and politicians are closer and with some personal overlaps (e.g., Bronislaw Geremek in Poland) as in Swedish social engineering in the 1930s. While sociology is a shrinking discipline in the developed world, it has a growing market in developing countries.

The ambiguity or interplay between politics and science is characteristic for both Weber and Gunnar Myrdal (1898–1987), who offers an 'operationalization' of Weber/Rickert. Myrdal's research in the mid-1930s is dedicated to educational social engineering; and in Myrdal & Myrdal, Kris i Befolkningsfrågan (*Crisis in the Population Question*, 1934) he deals with demographic aspects of a sustainable welfare state. Housing, education, unemployment, nutrition, health care, etc., are dealt with from a national perspective. The book from 1934 is not yet translated into English, but is partly available in Alva Myrdal's *Nation and Family* (1941).

Gunnar Myrdal is both a scientist and a politician, pursuing double careers. The problem of science and values – to bridge David Hume's gulf between 'is' and 'ought' – found a pragmatic solution in Myrdal, with his argument that the chosen explicit value premises providing ultimate top-values in rationalizing value hierarchies for instrumental policy formation, should be 'significant' and 'relevant'. One way to become efficient and 'make a difference' is to connect with contemporary social movements, such as the labor movement. Weber was more like 'dry swimming' compared to Myrdal's praxis orientation, promoting intersubjectivity and testability.

Myrdal was obsessed with how to avoid value bias throughout his life, a recurrent theme in his production from the late 1920s to the early 1970s.

The main source of inspiration was the Swedish 'nihilist' philosopher Axel Hägerström (1868–1939). In his inaugural lecture ('On the Truth of Moral Propositions', in Hägerström 1964) as professor in practical philosophy at Uppsala University in 1911, he claimed that there is no science in morals, only about morals. This lecture is the first coherent formulation of a negative-value ontology, although it had high affinity with similar strands in Cambridge (G.E. Moore) and Vienna (or Graz: Alexius Meinong).

Myrdal, who also was a do-gooder and compassionate world improver and active social engineer and public intellectual, illustrates that there is no necessary contradiction in combining this with a negative-value ontology and non-cognitivist value sentence theory. Value judgments might be scientifically meaningless but there is no harm in promoting them, as long as it is not in the form of 'hidden agendas'.

The difference with Weber is that there is an element of infinite regress in Weber's neo-Kantian approach: we cannot know the borders of rational scientific knowledge formations in the future; we can only not today by scientific means judge between values. To Hägerström and his pupils, values are cognitively meaningless, just as coughs or sneezes. The idea that law is morally binding appears to Hägerström as superstition and magic.

His most dedicated pupils are within the school of Scandinavian Legal Realism (Karl Olivecrona, Vilhelm Lundstedt, and Alf Ross), a school to which also Myrdal belonged. The orthodox adherents would not write about rights but 'rights' with quotation marks, or instead adding 'the realities this term implies'. Rights and duties are artifacts, an instrumental human invention for the pursuit of happiness in a *Rechtsstaat*.

'Scientific value relativism' is a common label for both Weber and Myrdal. Arnold Brecht (1959) is the best source for its provenance and characteristics. Brecht's *Political Theory: The Foundations of Twentieth-Century Political Thought* (1959) is one

of those books without a 'best before' date. Brecht is an excellent example of what he called the 'gulf-doctrine', codifying the scientific method and its limits, yet motivated by consolidating peace.

The predicament in post-Enlightenment polytheism with its new anxiety of choice is common to Weber/Rickert and Myrdal/Hägerström. In a secularized world we cannot unite upon any true values. We might, at best, establish some working 'community of assumption' in order to enjoy a civilized order and perhaps, in the spirit of Bentham and Kant, discuss various tentative or postulated highest values, such as 'the pursuit of happiness'. 'Public welfare' was also popular in post-Jacobine Enlightenment. The dignity of the human individual as a cultural being is an alternative close to both Kant and Weber. But the 'Archimedean point' has to be postulated.

Myrdal emphasizes and applies explicit value premises in his main work *An American Dilemma* (1944), in ambitious appendices.

Myrdal (1944) is a pivotal text for understanding science versus politics as interrelated activities, communicating bowls. It is a 'commodified' investigation financed by the Carnegie Foundation, with the explicit goal of promoting human and minority rights, which is the reason Myrdal is so very ambitious providing detailed exposure of the value premises at work.

Weber was also a public intellectual *avant la lettre*, with many critical contributions to the liberal Frankfurter Zeitung during World War 1. He was a loyal patriotic dissident on the verge of *lese-majesty*.

The 'enemies' of objectivity are numerous, for instance so-called Action research, in which trained nurses could turn themselves to activists in social policy matters and scholars declare solidarity with their research objects. Especially in anthropology, it is a temptation for researchers to identify with their object of research and 'go native'.

Feminist-inspired research deals with gender issues in a way that does not prioritize the criteria of Karl Popper's (1902–94) critical rationalism and the ideal of organized skepticism. We also encounter various forms of dogmatism. Karl Marx was an eminent scholar but it is hard to ignore that his theory about the contradictions in ideal-typical capitalism cannot meet testability criteria and will not easily match Popper's fallibilism, something in common to most macro-theories, due to the option to 'anticipate the consequences'.

Science is only one way to knowledge, aside from revelation. Even Weber in a letter late in life, plays with the idea of being a 'privately' religious person. His problem horizon is defined by Troeltsch's work on 'The Problems of Historicism'. Troeltsch's theology deals with the loss of meaning (the theodicy problem) which is captured by Weber in the metaphor of the 'iron cage' and which calls for values but throws us into polytheism or 'perspectivism'. In a letter to Ferdinand Tönnies (1855–1936), Weber combines a searching attitude in matters of personal conviction and the scientific and anti-metaphysical creed (Weber, 19 February 1909 in MWG II/6: 63 *et passim)*. Weber here makes a very clear demarcation between faith and science, yet indicates that on the personal level he is neither anti-religious, nor a religious, even if he is religiously unmusical (MWG II/6: 65).

Before the objectivity problem becomes urgent with antagonistic world-views in struggle using different 'language games', nascent social science was busy mapping its territory by use of refined survey techniques, which was in the United States combined with a Lutheran reform creed. Being a priest is the most popular second career choice for US sociologists, and many started as social workers. In the United Kingdom, sociologists have a different *habitus*, playing snooker and watching soccer games.

Philanthropy played a significant role in early social science, with Carnegie financing the huge educational project of which Myrdal's *An American Dilemma* was a part, and the Laura Spelman Rockefeller foundation financed the first chair in social policy in Sweden and contributed also to the budget of some Kaiser Wilhelm Institutes (today Max Planck) in Germany. The link to fast urbanization and industrialization in a society of mass production and mass consumption is a backdrop and surveys in demand. 'Fordism' is a concept grasping the interest of big enterprise to be aware of the predicament of the human being. Henry Ford's company had its own sociological department.

Political economy offers applications for political decisions, based on improved cognition. The US anti-Trust legislation could be seen as an application of the Marxian analysis of the logic of the capitalist mode of production. After the great depression, in 1929, anti-cyclical 'Keynesian' policy was successfully implemented by various regimes, in Sweden, Germany, and the United States. Unthinking the political dimension of Milton Friedman (1912–2006) would be unnatural. There is – for better or worse – an invasion by rational choice in the humanities affecting policy making also.

Today the research councils are assigned the task to canalize tax payers' money into planned research, leaving little room for serendipity. The freedom of research is limited to methods and results, but in reality there is no longer the choice of topics. The NPM (new public management) ideal now operates also on the European level. Conformism erodes autonomy; scholarship being transformed into 'scholarshop'.

The universities are hosting 'rebels in search of a cause', some of them 'Trojan horses' not sharing the value assumption of uncompromising search for truth. Extramural interests are on the board of higher institutions of research and learning. In Sweden the Chair on the Board is appointed by the government.

After *die Wende* there was a *Stunde Null* with an open future and many suggestions about future designs. The university system in BRD was reorganized. What the case of post-World War II Germany illustrates is that science can co-exist with various regimes, when its internal norm system is not damaged. This was, however, the case in social science and the humanities, resulting in a liturgic 'new speech', although here also scholarship in the academy remained competitive, for instance in history writing and linguistics.

In present-day Europe, politicians tend to see the universities as a means for social goals and economic growth, rather than intellectual development. The era of 'Bologna' invites moral confusion within the universities and the financial system, with science councils where researchers have to apply invites to self-corrupting tactics, according to critics. Syllabuses are also increasingly streamlined in a way that puts the academic teachers at disadvantage and the evaluation industry flourishes. MOOC (massive open on-line course) further

erodes the old 'Humboldtian' ideals, but increases dissemination of knowledge.

Events in Berkeley, Paris, and more places in the 1960s indicated the new era of the 'megaversity', to use a neologism by the Californian educator Clark Kerr (1911–2003), with ensuing 'polytechnic' orientation of the universities. Kerr's dismissal as President of the University of California by Ronald Reagan, moreover, being an example of state power intervening in the world of research and teaching.

Max Weber's doctrine with its demarcation between scholarship and politics remains the standard position, but is recurrently under siege. His pupil Georg Lukács (1885–1971) is one prominent example, in Die Zerstörung der Vernunft (The Destruction of Reason, 1953).

Science and Religion

This article is a revision of the previous edition article by C.A. Russell, volume 12, pp. 13621–13625, © 2001, Elsevier Ltd.

Abstract

The relationship between science and religion is contingent upon at least three factors: the period of time in question, the religion of interest, and the views of specific individuals. This article illustrates that an accurate understanding of the relationship between science and religion can only be discerned in the light of knowledge of these three factors. The article also notes the growing interest in the scientific study of religion.

The relationship between religion and science is complicated (Brooke, 1991). It is complicated by the fact that both religion and science have changed over time, and by the fact that neither may be said to constitute singular, uniform entities (*see* Science, Sociology of). While the boundaries of science are somewhat porous and it can be difficult to demarcate what should and should not be included as science (Evans and Evans, 2008), 'religion' is a broad term that refers to thousands of diverse organizations (Cho and Squier, 2008). Additionally, individuals can and do think about both science and religion in multifaceted ways (Baker, 2012; Sherkat, 2011). Thus, the relationship between religion and science is complex because it is contingent upon at least three factors: the time period in question, the religion of interest, and the individual. Each of these will be discussed in turn, as well as the increasing interest in studying religion scientifically.

Time Period

The specific methodology and concomitant knowledge for understanding the natural world referred to nowadays as 'science' are relatively recent human developments. Humans have, for thousands of years, attempted to understand the natural world, but not in the exacting way employed nowadays by scientists. Evidence for interest in understanding the natural world can be seen in famous monuments built in prehistoric times (i.e., *c.*3000 BCE), like Stonehenge and Newgrange; these monuments appear to be oriented relative to astronomical phenomena, reflecting attempts to understand the movement of celestial bodies.

Some of the earliest and most well-known efforts to systematize knowledge about the natural world come from the ancient Greeks (Roger, 1986). While they did use some experimentation not unlike that employed by scientists nowadays (Geymonat, 2010), most of their ideas were derived from speculation, contemplation, and introspection (Roochnik, 2004), which are approaches to understanding the world more commonly referred to nowadays as philosophy, not science. However, it was speculation about the natural world that ultimately became the science of the modern age. Speculation about the natural world was originally called 'natural philosophy' (Brooke, 1991). Natural philosophy evolved over thousands of years – from the ancient Greeks to the Renaissance and Enlightenment thinkers – until it eventually became what we call as science. During that evolution, the way that natural philosophy was conducted changed (Lindberg, 1986). Early natural philosophy would have included both empirical investigation, like observing the paths of celestial bodies, but also introspective contemplation or speculation, like contemplating similarities between humans and other living things. Over time, stricter criteria for observation and speculation were developed, leading to the Renaissance, the project of modernity, and ultimately to the more rigorous empiricism of modern scientific endeavor (*see* History of Science).

This brief history of science and its evolution is noted here in order to illustrate that what people typically call science has not always been the exacting and precise discipline it is today. This becomes even more apparent when the relationship between religion and science is examined.

Religion, from a historical standpoint, predates natural philosophy (Lindberg, 2007; *see* Religion, History of). Yet, the two are not entirely dissimilar, particularly in antiquity (Brooke, 1991). Religion, broadly, is collective beliefs relative to the supernatural – collective because religions are social institutions and supernatural because religions incorporate beliefs and ideas that fall outside of nature. However, the distinction between natural and supernatural is not fixed; it is a dynamic distinction based on the accumulation of knowledge. The use of religion vis-à-vis natural philosophy to explain the natural world is likewise dynamic. When very little was understood about the natural world, as was the case in prehistoric times and antiquity, religion was often invoked to offer such explanations. For instance, the occurrence of a flood or tsunami, while fully understood by modern science, would not have been explainable by natural philosophers thousands of years ago (Dundes, 1988). Without a naturalistic (i.e., nonsupernatural) explanation, a supernatural one might be suggested, like any of the dozens of documented flood myths that are widespread among religions around the world, e.g., the epic of Gilgamesh or the Noachian flood of the Bible/Torah, that invoke the wrath of a deity to explain the sudden, devastating influx of water (Dundes, 1988). Thus, when very little knowledge about the natural world existed, religion was invoked to offer explanations. In the ancient world, things like earthquakes, rain, stars, floods, storms, and even life and death were all explained through religion, because so little was known about the natural

world (Campbell and Moyers, 1991). However, as natural philosophy expanded and eventually evolved into modern science, naturalistic explanations for natural phenomena increased, shrinking the domain of religious explanations (Grant, 1986). While many modern theologians argue against the idea that religion now offers a 'god of the gaps' – i.e., god and religious explanations are inserted into the gaps of scientific knowledge (Dixon, 2008; Evans and Evans, 2008), most religions no longer suggest supernatural explanations for natural phenomena that do not have alternative explanations in scripture (e.g., lightning strikes or volcanic eruptions).

The depiction of the relationship between religion and science in the previous paragraph, while necessary to illustrate how science and religion are different, is overly simplistic. It suggests that religion and science are distinct and incompatible. While they are distinct epistemologies and in many ways incompatible (see below), this has not always been the case. Early natural philosophers would often rely in part on supernatural phenomena as explanations for natural phenomena when naturalistic explanations were not sufficient. Many natural philosophers were motivated by their religious beliefs to pursue an understanding of natural phenomena, often with the aim of supporting their religious beliefs. This was the case for one of the most famous scientists, Isaac Newton. While unorthodox in his religious views, Newton was driven by his belief in the supernatural to try to discern order in the universe (Popkin et al., 1999). Upon finding such order, Newton did not stop believing in the supernatural but rather felt that he had helped to illustrate that there was a divine order in the movement of planets and stars (Westfall, 1986; Jacob, 1986). Many natural philosophers/scientists were motivated by their religious worldview to investigate nature, and many of these individuals retained their religious beliefs – though often in a modified form – after advancing science through discovery (Westfall, 1986; Brooke, 1991).

Another famous scientist, Galileo, is often invoked to argue that the relationship between religion and natural philosophy was hostile, given his imprisonment and forced recanting of the heliocentric model of the solar system he proposed, by the Roman Catholic Church. Yet, even that famous case was complicated by the context in which it occurred – the Protestant Reformation had just begun and the Catholic Church became less tolerant of alternative views as a result (Shea, 1986; *see* Reformation and Confessionalization). The Roman Catholic Church did ban specific books, and the threat of punishment from the Church was an ever-present concern for many natural philosophers during the Late Middle Ages and through the Renaissance (Shea, 1986; *see* Renaissance). Yet, there were also many natural philosophers who were also religious functionaries – e.g., priests and monks – during the late middle ages and early Renaissance (Ashworth, 1986). In short, the historical relationship between religion and science was never perfectly distinct nor was it entirely oppositional.

The complicated relationship between religion and science is also apparent in other religious traditions, like Islam. Islam had a period of significant scientific advancement, often referred to as the Islamic Golden Age (*see* Historical Thought and Historiography: Islamic Tradition). During this time, scholars throughout the Muslim world made significant advances in science and, like Newton, were often inspired by their religion to do so. For instance, Al-Khwarizmi developed algebra in part to help solve Islamic inheritance laws (Gandz, 1938). Likewise, advances in astronomy, geography, and trigonometry were motivated in part by the desire to be able to accurately determine the direction of the Qibla for Salah prayers (Gingerich, 1986). While support for scientific endeavors began to wane in the Muslim world in the 1500s, there was a period of time during which Islam strongly motivated individuals to pursue a better understanding of the natural world and there are many Muslims today who see no conflict between modern science and their religion (see below).

It is only since about the middle of the nineteenth century that the relationship between science and some religions has been formulated as a distinctly antagonistic one (Dupree, 1986; Gregory, 1986; Numbers, 1986). This leads to the second factor that must be considered when examining the relationship between science and religion – specific religious institutions.

Religion of Interest

'Religion' refers to the broad group of organizations that various scholars have suggested should be grouped together. What these organizations have in common is that they, in some way, relate to the supernatural. The supernatural would include gods, angels, demons, spirits, or essences that exist outside of the natural or empirically detectable world. Thus, by definition, religions include elements that lie outside the domain of science, which is concerned with the natural world. As noted above, the relationship between the natural and supernatural is dynamic, as many things that were once thought to be supernatural – e.g., lightning and the origins of species – have now been shown to be natural phenomena.

More importantly, there is a great deal of diversity within the broad category of religion. There are numerous ways to distinguish between different types of religions. One way to categorize religions is based on their relative geographic origins – distinguishing between Eastern and Western religions. Another way would be to group religions into broad families that are historically, organizationally, and theologically similar, e.g., Hinduism, Buddhism, Judaism, Christianity, Islam, and other religions. These classification schemes are useful for understanding historical similarities between religions, but there is a better way of understanding religions when it comes to the relationship between science and religion today.

Originating in the US in the late nineteenth and early twentieth centuries was a split among Protestant religions over the acceptance of science (Antoun, 2008; *see* Christianity: Evangelical, Revivalist, and Pentecostal). Some Protestant religions embraced the findings of the increasingly rigorous scientific community. As a result of embracing these findings, like Darwin's theory of evolution, these religions began to 'liberalize,' adjusting their supernatural beliefs according to the findings of modern science (Chaves, 1997; *see* Liberal Christianity). A literal interpretation of the Bible morphed into a metaphorical interpretation, as stories like Adam and Eve being the first humans on the planet were no longer tenable in

light of the findings of geology, biology, and other scientific disciplines (Yandell, 1986). The Protestant religions that accommodated science came to be viewed as 'liberal' religions. But not all religions were willing to accommodate science. Some rejected what they saw as capitulation to modernity and instead advocated a return to the 'fundamentals' of religion. These religions came to be viewed as 'fundamentalists.' While originally a term used to describe just this group of Protestants, the term is now more widely used to describe any religious group that exhibits specific characteristics, namely scriptural literalism and black and white thinking (Antoun, 2008). Holding a literalistic view of scripture results in conflict with science, as science has shown that various aspects of the Bible (but also other scriptures, like the Quran, the Bhagavad Gita, the Book of Mormon, etc.) are inaccurate when interpreted literally.

There has been, then, a split among religions over acceptance of science. While this split is not as clean as the previous paragraph suggests – some religions lie in between, accepting some aspects of science but rejecting others (Cragun, 2013) – the split illustrates that the relationship between religion and science is religion-specific. Some religious groups, like Reformed Judaism or the United Church of Christ, largely accept the findings of modern science. Other religions, like Southern Baptists and many Pentecostal congregations, reject the findings of modern science that conflict with their literalistic interpretation of scripture. Likewise, within Islam there are individuals who are more receptive to science and individuals who reject tenets of modern science that contradict their interpretation of their religion. Discerning which religions have embraced modern science and which have rejected it is somewhat easier in the Christian West as some of the divisions between religions have been over these very issues (e.g., Lutheran divisions in the US are based on this distinction). However, this type of distinction, between fundamentalist, moderate, and liberal interpretations of religion can be observed in every major religious tradition, including Judaism, Islam, Buddhism, Christianity, and Hinduism. In short, without knowing which specific religion is of interest, and perhaps even which religious congregation (assuming a congregational structure), it is difficult to know exactly how religions view modern science. Some religions embrace it; others reject it; and still others embrace some elements of science but not all of it.

Individuality

Yet, even recognizing the distinctions that exist between religions, it has increasingly been shown that individual members within religions are more or less receptive to science, regardless of the formal teachings or doctrine of the religion (Baker, 2012; Sherkat, 2011). Recent research has shown that denominational distinctions are breaking down and that there is greater diversity within religions than between religions. **Table 1**, using data from a dozen countries around the world, illustrates the diversity that exists within religious traditions. It shows that even within the same religion, attitudes toward science vary considerably.

As the table illustrates, many Muslims, Buddhists, Hindus, Protestants, and Catholics around the world are more and less receptive to science. It is the case nowadays that fundamentalist and liberal Catholics sit side-by-side during Mass. Likewise, there are Muslims in the Middle East who are scientists and accept the major tenets of modern science, yet attend Friday prayers with fundamentalist Muslims who reject evolution. Knowing an individual's religion will increase the odds of accurately predicting their views of science (Sherkat, 2011), but such knowledge will not allow for perfect predictions.

The Scientific Study of Religion

Of final note, despite the complex relationship between science and religion, in the last two centuries, religion itself has increasingly become an object of scientific investigation. Such investigation can focus on the origins of religion (Barrett, 2004; Atran, 2002), the evolution of religions and religious concepts over time (Atran, 2002; Armstrong, 1994; *see* Religion: Evolution and Development), the present state of religions

Table 1 View of science and faith of members of most popular religion in various countries

	We depend too much on science and not enough on faith		
Most popular religion/country	*Disagree (1–4) (%)*	*Neutral (5) (%)*	*Agree (6–10) (%)*
Buddhists in Japan	24	22	54
Catholics in Brazil	56	20	24
Catholics in Poland	22	21	57
Evangelical Church in Germany	35	20	45
Evangelical Lutheran Church of Finland	30	14	56
Hindus in India	30	na	70

(Chaves, 2011), and the psychology and biology of religious people (Molendijk and Pels, 1998; Ashbrook and Albright, 1997; *see* Psychology of Religion). The scientific study of religion has led to the understanding that religion is a social construction (Berger, 1990), that religion evolves in light of both internal and external pressures (Chaves, 1997; Lawson and Cragun, 2012), that human evolution and psychology contribute in intriguing ways to religious beliefs (Atran, 2002), and has even begun to predict the potential future of religion (Bruce, 2002).

Conclusion

Historically, science and religion were different from what they are today. Science was far more speculative and less rigorous in its approach to understanding the natural world than it is today, and it was also often engaged in by religious people who were pursuing it in the interest of justifying their religious beliefs. While religions did, at times, oppress scientific inquiry and scientists, it is not accurate to state that religion and science were always opposed. Today, the same relationship holds. Some religions – fundamentalist religions – reject elements of science they believe contradict their religious beliefs. But many other religions embrace modern science, modifying their understanding of or jettisoning outright elements of their religion that contradict scientific findings. And within any religion, individuals may be more or less receptive to science than the religion's own doctrine. Science has also begun to turn its unflinching gaze toward religion, revealing that even belief in the supernatural is likely a natural phenomenon.

Science and Social Movements

Andrew Jamison, Aalborg University, Aalborg, Denmark

Abstract

The relations between science and social movements are multifaceted. New frameworks for scientific activity have often emerged as part of broader political and social struggles. Social movements have also provided audiences, or new publics, for the spreading and popularization of scientific findings and ideas, as well as critical perspectives on both the form and content of science and of the uses to which science has been put. Finally, it can be suggested that many social movements are themselves producers of science, in that they provide alternative modes of knowledge production that contend with more established or hegemonic modes.

Introduction

The social movements that are discussed in this article refer to major political processes of popular mobilization that have significant societal significance, and include organized forms of protest as well as broader and more diffuse manifestations of public opinion and debate. In relation to science, social movements conceived in this way can be seen to have served as seedbeds for new modes of practicing science and organizing knowledge more generally, and also as sites for critically challenging and reconstituting the established forms of scientific activity.

Since they fall between different academic specializations and disciplinary concerns, the relations between science and social movements have tended to be a neglected subject in the social sciences. For students of social movements in sociology and political science, the relations to science have been generally of marginal interest and received little systematic attention, while in science and technology studies, social movements usually have been regarded more as contextual background than as topics of investigation in their own right. Considering their potential significance as 'missing links,' both in the social production of knowledge and in broader processes of political and social change, however, the relations between science and social movements deserve closer scrutiny. For one thing, new ideas about nature and society have often first emerged outside the world of formal scientific activity, within broader social and political movements. Social movements have also often provided audiences, or new publics, for the spreading and popularization of scientific findings and results. Movements of religious dissent were among the most significant disseminators of the new experimental philosophy in the mid-seventeenth century, for example, while, in the nineteenth and twentieth centuries, new approaches to medicine, social relations, gender roles, and the environment found receptive audiences within social and political movements. Most recently, in relation to such issues as climate change, the different attitudes to science in contending political and social movements have played a key role in the international public debate (Jamison, 2010).

What Is a Social Movement?

There Is little agreement among those who study social movements about what a social movement 'really' is. Definitions depend on which movements are seen as typical or most important, what kind of terminology or conceptual framework is applied, the particular research questions being addressed and, not least, the situation, or standpoint of the researcher (Della Porta and Diani, 2006). Since Neil Smelser (1962) in his classic work, *Theory of Collective Behavior*, divided movements into 'results-oriented' and 'values-oriented' types, there has been a bifurcation among the students of social movements, namely, between those who focus on what might be termed movements in the streets, that is, explicit protest movements, versus those who focus on movements in the mind, that is, cultural and intellectual movements. However, the various definitions that have been most actively applied in the scholarly literature can be said to share certain common features or elements that will be used to provide a 'working definition' of social movements for the purposes of this article.

On the one hand, a social movement is a collective form of social behavior that is explicitly organized for political action. A social movement is the process by which human and material resources are mobilized to try to affect political change (an influential recent discussion is McAdam et al., 2001). They make use of what Herbert Kitschelt (1986), in his analysis of antinuclear movements in the 1970s, termed 'political opportunity structures' in pursuit of one or another political cause. Social movements tend to manifest themselves through publicly recognized forms of protest, or direct action, but those acts do not themselves make a social movement. They need to be linked or connected to one another in some way, organized and coordinated by means of a common platform or program. This provides what has been termed a 'collective identity,' a set of values, precepts, or beliefs that empower those who share them and identify with them. These matters of collective identity formation have been most influentially theorized and studied by Alain Touraine and Alberto Melucci and their students and colleagues (cf Touraine, 1981, 1988; Melucci, 1996).

On the other hand, a social movement is something distinct from more formalized political parties, social institutions, or other established kinds of politics, in that it has a more informal character than established political and social activities; in this regard, social movements are related to what Ulrich Beck (1992) has termed 'subpolitics.' Many

 http://dx.doi.org/10.1016/B978-0-08-097086-8.85022-9

theorists have attempted to distinguish movements from institutions, organizations, and political parties (perhaps most famously Alberoni, 1984), and a recurrent effort in social movement studies has been to analyze processes of institutionalization and professionalization. In recent years, social movements have come to be ever more likened to, and conceptualized as, networks, and attention has been given to distinguishing between the different kinds of networking, brokerage and (inter)mediation that goes on in social movements (e.g., McAdam and Diani, 2003). In many contemporary social movements, not least those related to climate change, much of this networking activity is now conducted 'virtually' via electronic communication and the Internet (Garrett, 2006).

A third element of almost all theories of social movements is the understanding that social movements are more than 'merely' political phenomena, and that they involve some form of what Jürgen Habermas has influentially termed communicative action. As in other fields of social science, there has been an increasing interest in these more communicative, or cultural, aspects of social movements (cf Goodwin and Jasper, 2004). Many social movement analysts use the concept of framing to discuss these matters (Snow and Benford, 1988; Benford and Snow, 2000), while for others the role of passions and emotions has come to be emphasized (cf Goodwin et al., 2001). Other theorists, usually within anthropology, have focused explicit attention on the uses of knowledge by social movements, especially the uses of so-called indigenous knowledge by social movements in non-Western countries (e.g., Aparacio and Blaser, 2008; Escobar, 2008).

The cognitive approach to social movements (Eyerman and Jamison, 1991) makes use of the terms 'cognitive praxis' and 'movement intellectuals' to emphasize the role of knowledge making in social movements, and to characterize the people who are most actively involved. Cognitive praxis is defined as the linking, or integration of ideas, ideologies, and/or world view assumptions (a cosmological dimension) to particular activities or forms of action, including technical development, information dissemination, and practical demonstration of both protest and constructive alternative (a technological dimension). The experimentation with renewable energy that took place in the environmental movements of the 1970s is only the most recent example of the kind of alternative technology development that takes place in social movements (Jamison, 2013). The movement is seen as providing an organizational dimension, a public space, for integrating the cosmology and the technology in processes of collective learning, and it is their cognitive praxis that makes social movements particularly important in the constitution and reconstitution of science and technology (Jamison, 2006). Eyerman and Jamison (1998) broaden the cognitive approach to encompass cultural practices and, by so doing, focus attention on the role that the 'mobilization of tradition' plays in the collective activities of many social movements. It is the mobilization and (re)invention of different traditions of ideas, beliefs, and ideologies that often plays an important role in attracting active participation and involvement in social movements.

Historical Perspectives

A fundamental insight of the sociology of knowledge, as it developed in the 1920s and 1930s, was to suggest that modern science emerged in the seventeenth century out of a more all-encompassing struggle for political freedom and religious reform (Scheler, 1980 [1924]; Merton, 1970 [1938]). What eventually came to be characterized as modern science represented an institutionalized form of knowledge production that, at the outset, had been inspired by more sweeping social and political transformations. The historical project of modernity did not begin as a new scientific method, or a new mechanical worldview, or, for that matter, as a new kind of state support for experimental philosophy in the form of scientific academies. As for the Reformation, it arose as a more deep-seated challenge to traditional ways of thought in social and religious life. It was a protest against the Church (which is why the members of the movement were called protestants), and it was an encompassing social and cultural movement that articulated and practiced alternative, or oppositional, forms of religion, politics, and learning as part of its political struggle (Mandrou, 1978). The teachings of Paracelsus, Giordano Bruno, and Tomaso Campanella, to name some of the better known figures, combined a questioning of established religious and political authority with an interest in scientific observation, mathematics, mechanics, and technical improvement (Merchant, 1980). But, as the broader movements were replaced by more formalized institutions in the course of the seventeenth century, the political and social experiments came to be transformed into scientific experiments; the political and religious reformation, tinged with mysticism and filled with mistrust of authority, was redefined and reconstituted, at least in part, as a scientific revolution (see **Table 1**).

In the late seventeenth and early eighteenth centuries, the scientific 'aristocracy' that had emerged in London and Paris at the Royal Society and the *Academie des Sciences* was challenged by dissenting groups and representatives of the emerging middle classes, some of whom fled from Europe to the colonies in North America, and some of whom established scientific societies, often in provincial areas in opposition to the established science of the capital cities.

Table 1 A schematic representation of the scientific revolution from movement to institution

From movement	*To institution*
Social reform	Reform of philosophy
Millenarian vision	Experimental program
Connection to radical politics	Rejection of politics
Decentralized structure	Central academy
Democratic/open to all	Elitist/professional
Spiritual (absolute) knowledge	Instrumental (probabilistic) knowledge
Technical-economic improvement	Scientific development
Informal communication	Formal communication
Pamphlets, correspondence	Journals, papers

Many of them shared with the academicians and their royal patrons a belief in what Max Weber termed the protestant ethic, that is, an interest in the value of hard work and the virtue of making money, and most had an interest in what Francis Bacon had termed 'useful knowledge.' The social movements of the enlightenment objected, however, to the limited ways in which the Royal Society and the Parisian Academy had organized the scientific spirit and institutionalized the new methods and theories of the experimental philosophy. The various attempts to democratize scientific education in the wake of the French Revolution and to apply the mechanical philosophy to social processes – that is, to view society itself as a topic for scientific research and analysis – indicate how critique and opposition helped bring about new forms of scientific practice. Adam Smith's new science of political economy developed in the Scottish hinterland, and many of the first industrial applications of experimentation and mechanical philosophy took place in the provinces, rather than in the capital cities, where the scientific academies were located (Russell, 1983).

Many of the political and cultural trends of the nineteenth century – from romanticism and utopianism to socialism and populism – also began as critical movements that at a later stage, and in different empirical manifestations, came to participate in reconstituting the scientific enterprise (cf Jamison et al., 2011). Romanticism, for example, first emerged as a challenge to the promethean ambitions of science, in the guise, for example, of Mary Shelley's Doctor Frankenstein, while socialism, in the utopian form promulgated by Robert Owen, was a reaction, among other things, to the problematic ways in which the technological applications of scientific activity were being spread into modern societies. Romantic writers and artists, like William Blake, Johann Goethe, and later Henry David Thoreau, were critical of the reductionism and cultural blindness of science and of the 'dark satanic mills' in which the mechanical worldview was being applied. They sought to mobilize the senses and the resources of myth and history in order to envision and create other ways of knowing (Roszak, 1973). Some of their protest was transformed into constructive artistic creation, and later in the century, the romantic revolt of the senses inspired both the first waves of environmentalism in the form of conservation societies and the emergence of a new kind of holistic scientific discipline, to which was given the name ecology: household knowledge.

In the late nineteenth century, the labor movement also sought a deep-going, fundamental political, and cultural transformation of society, but it would see its critical message translated, in the twentieth century, into packages of reforms and a more welfare-oriented capitalism, on the one hand, and into the 'scientific socialism' of Lenin and Stalin, on the other (Gouldner, 1980). Once again, however, science benefited from this institutionalization of the challenge of social movements; the knowledge interests of the labor movement, for example, entered into the new social science disciplines of economics and sociology. A political challenge was once again transformed into programs of scientific research and state policy, but while new forms of scientific expertise were developed, little remained of the broader democratization of knowledge production that the labor movement, in its more radical days, had articulated.

In the early twentieth century, the challenge to established science was mobilized most actively in the colonies of European imperialism, as well as in the defeated imperialist powers of Germany and Italy; the critique was primarily of scientific civilization writ large, and of what Mohandas Gandhi in India called its 'propagation of immorality.' In the name of modernism, science stood for the future and legitimated, in the colonies as well as in Europe, a wholesale destruction of the past and of the 'traditional' knowledges – the other ways of knowing – that had been developed in other civilizations (Tambiah, 1990). These social movements had an impact on the development of political ideology on both the right and left, but also inspired new sciences of ethnography and anthropology, as well as the sociology of knowledge. Even more important perhaps were the various attempts to combine the artisanal knowledges of the past and of other peoples with the modern science and technology of the present in new forms of architecture, design, and industrial production. Many of the regional development programs of the 1930s and 1940s, in Europe and North America, can trace their roots back to the cultural critique of modernism that was inspired by the Indian independence movement and by such 'movement intellectuals' as William Morris and Patrick Geddes in Britain. Both Roosevelt's New Deal and the Swedish model welfare state can be said to have mobilized critical perspectives in their projects of social reconstruction.

Science and the 'New Social Movements'

In recent decades, social movements have also served to challenge and reorient the scientific enterprise. Of the so-called new social movements of the 1960s and 1970s (anti-imperialist, environmentalist, feminist, and identity movements) have emerged a range of alternative ideas about science, in form, content, and meaning, that have given rise to new scientific theories, academic fields, and technological programs (Schiebinger, 1993; Harding, 1998). Out of critique have grown the seeds of new, and often more participatory, ways of sciencing – from technology and environmental impact assessment to women's studies, queer theory, and postcolonial discourses. What were protest movements of radical opposition in the 1960s and 1970s largely have been emptied of their political content, but they have given rise to new branches of, and approaches to, science and technology.

The new social movements rose to prominence in the downturn following a period of institutional expansion and economic growth. They emerged in opposition to the dominant social order and to its hegemonic scientific technological regime, which had been largely established during and immediately after World War II (Touraine, 1988). The war led to a fundamental transformation in the world of science and technology, and to the emergence of a new relation, or contract, between science and politics. The war effort had been based on an unprecedented mobilization of scientists to create new weapons, from radar to the atomic bomb, and

to gather and conduct intelligence operations. In the process, 'little' science was transformed into big science, or industrialized science.

Especially important for the new social movements that were to develop in the 1960s and 1970s was the fact that scientific research was placed at the center of postwar economic development. Many of the economically significant new products – nylon and other synthetic textiles, plastics, home chemicals and appliances, and television – were based directly on scientific research, and the new techniques of production were also of a different type: it was the era of chemical fertilizers and insecticides, of artificial petrochemical-based process industries, and food additives. The forms of big science also differed from the ways in which science had been organized in the past. The big science laboratories – both in the public and in the private sectors – were like industrial factories, and scientific-technical innovation came to be seen as an important concern for business managers and industrial organizers. The use of science in society had become systematized, and, as the consequences of the new order became more visible, new forms of mistrust and criticism developed (Jamison and Eyerman, 1994).

One wing of the public reacted to the destruction of the natural environment, what an early postwar writer, Fairfield Osborn, termed 'man's war with nature.' The exploitation of natural resources was increasing and, in the 1940s and 1950s, it began to be recognized that the new science-based products were more dangerous for the natural environment than those that had come before. But it would only be with Rachel Carson, and her book *Silent Spring* in 1962, that an environmental movement began to find its voice and its characteristic style of expression. It was by critically evaluating specific instances of scientific technology, particular cases of what Osborn had called the 'flattery of science' that the environmentalist critique would reach a broader public. Carson singled out the chemical insecticides for detailed scrutiny and assessment, but her point was more general. Carson's achievement was not only to direct the methods of science against science itself, but also to point to another way of doing things, the biological or ecological way – what she called in her book the road not taken.

Another source of inspiration for the new social movements came from philosophers and social historians who questioned the more general impact of science on the human spirit. It was one-dimensional thinking that critical theorists like Herbert Marcuse reacted against, the dominance of an instrumental rationality over all other forms of knowing. For Lewis Mumford, another major source of inspiration, it was the homogenization of the landscape that was most serious, the destruction of the organic rhythms and flows of life that had followed in the wake of postwar economic growth, as well as the dominance of what he termed the 'megamachine,' the use of technology for authoritarian purposes.

In the 1970s, a range of new social movements, building on these and other sources of inspiration, came to articulate an oppositional, or alternative approach to science and technology (Dickson, 1974). The so-called new social movements represented an integrated set of knowledge interests, which combined the critique of Rachel Carson with the liberation dialectics of Marcuse and the direct democracy of the student movement. The new movements involved a fundamental critique of modern science's exploitative attitude to nature, as well as an alternative organizational ideal – a democratic, or participatory ideal – for the development of knowledge. There were also distinct forms of collective learning in the new social movements of environmentalism and feminism, as well as grassroots engineering activities that went under the name of appropriate or alternative technology. The social movements provided the setting for innovative forms of cognitive praxis, combining alternative worldviews, or cosmological assumptions with alternative organizational and practical–technical criteria.

In the case of environmentalism, the cosmology was, to a large extent, the translation of a scientific paradigm into a socioeconomic paradigm; in the 1970s, the holistic concepts of systems ecology were transformed into political programs of social ecology, and an ecological worldview was to govern social and political interactions. Technology was to be developed under the general perspective that 'small is beautiful' (in the influential phrase of E.F. Schumacher), and according to the assumption that large-scale, environmentally destructive projects should be opposed and stopped. At the same time, new contexts for education and experimentation and the diffusion of research were created in the form of movement workshops and, in the Netherlands, for example, in the form of science shops, which allowed activist groups to gain access to the scientific expertise at the universities (Irwin, 1995).

Since the 1980s, the cognitive praxis of the new social movements has been decomposed into a disparate cluster of organizations and individuals, through processes of professionalization and fragmentation. The movements were transformed into various kinds of professional expertise, which made it possible to incorporate parts of a particular movement into the established political culture, and to shift at least some of the members of the movement from outsider to insider status. The political struggles for civil rights, environmental protection, women's and sexual liberation, and ethnic and national identity have inspired new approaches to knowledge that have since been institutionalized and transformed into established scientific fields, such as environmental studies, women's studies, gay and lesbian studies, African-American studies, as well as in new areas of medicine and technology.

At the same time, science itself has been reconstituted, partly as a result of the critical perspectives and cognitive challenges posed by the new social movements of the 1960s and 1970s. Many of the postmodern theories in the cultural and human sciences have been inspired by the experiences of social and political movements. Of the alternative public spaces that have been created by social and political movements has emerged a new kind of scientific pluralism, in terms of organization, worldview, and technical application.

Science and Contemporary Social Movements

In recent years, there has developed a growing literature on science, technology, and social movements that has perhaps

been especially focused on local movements in such areas as food, agriculture, energy, and housing (Hess, 2007; Hess et al., 2008). There has also been significant attention devoted to health movements, particularly in relation to so-called patient groups (Epstein, 1996, 2008). There has also been interest directed to the movements associated with so-called climate skepticism, and their connections to neoconservative groups and movements (Austin, 2002; McCright and Dunlap, 2003; Jacques et al., 2008).

The relations between science and the movement for global justice that emerged in the wake of the antiglobalization protests of the late 1990s have also received attention by a variety of scholars. The global justice movement has been called 'a movement of movements' (Klein, 2000) and is composed of a variety of groups and individuals who have begun to take political action in order to protest the quite different kinds of negative consequences that they attribute to globalization.

There are at least three different kinds of submovements, or networks, concerned with global justice, which take part in various international gatherings that are sometimes said to represent the global justice movement (Jamison, 2010). These three strands, which often find themselves in conflict when it comes to particular topics, tend to mobilize different sorts of people with different sorts of grievances, and they tend to tap into different traditions of ideas. On the one hand, there are the parties, organizations, federations, and other institutionalized legacies of the so-called old social movements of the nineteenth and early twentieth centuries, the various outgrowths of populist and labor movements that have become integral parts of the political landscape.

A second important component of the emerging movement is based on the concerns of the new social movements of the 1970s, especially the movements for environmental protection and women's liberation. These movements have tended to become established fixtures in the contemporary world, primarily in the form of nongovernmental organizations, or NGOs. There is usually in these organizations a more businesslike, professional approach to politics, and, as is well known, these organizations, much like university science and engineering, have become dependent on external funding for most of their activity, which usually takes the form of specific projects related to what are sometimes termed 'single issues.'

In recent years, these 'old' and 'new' social movement-based organizations have been complemented by a newer wave, or generation, of activists, and by groups and organizations, which are often more confrontational than the older movements. Beginning in the 1980s, sometimes in the name of 'environmental justice,' these groups have often taken shape in direct opposition to particular manifestations of global injustice. In relation to science, the protests against biotechnology and genetically modified organisms (GMOs) in food and agriculture have been particularly active (Tokar, 2001; Schurman and Munro, 2010; Kinchy, 2012). In recent years, there have been attempts to arrange gatherings and manifestations, where the different component parts of the global justice movement can meet and discuss their concerns. These various 'social forums,' as they have come to be called, have taken place both at an international level (at world social forums, which have been held each year since 2000) and at more regional, national, and local levels, particularly in Europe (Fisher and Ponniah, 2003).

There are a number of tensions, not least generational and geographical, among the various components of the emerging movement, and, as might be expected, there are also some significant differences in regard to science. The remnants or residues of the older social movements, in the parties and organizations of the 'left,' tend to be favorable toward science and technology, while the institutional legacies of the new social movements of the 1970s, usually referred to as NGOs, tend to focus on particular issues or areas of concern. It is only a relatively small group of newer organizations and activists who have emerged to alert the public to the wide range of other challenges that science and technology raise in relation to global justice and economic inequality. For these people, science and technology are, for the most part, seen as connected with corporate expansionism. A representative of this kind of criticism is the Indian physicist-turned-activist Vandana Shiva, who has been one of the leading spokespersons for international protests against biotechnology and genetically modified foods (Shiva, 2000, 2005). Shiva's criticism is not about the science itself, but rather about the cultural contexts in which science is developed:

> The conflict over genetically engineered crops and food is not a conflict between 'culture' and 'science'. It is between two cultures of science: one based on transparency, public accountability and responsibility toward the environment and people and another based on profits and the lack of transparency, accountability and responsibility. (Shiva, 2000: p. 109)

This emphasis on the cultural dimension of science on the part of contemporary social movements is central to two recent studies. In *Fighting for the Future of Food*, Rachel Schurman and William A Munro (2010) characterize the struggle over biotechnology as a conflict between opposing 'lifeworlds,' and provide a detailed investigation of the values and ways of life of the anti-GMO activists, on the one hand, and 'agribusiness' companies and networks, on the other. In *Seeds, Science, and Struggle*, Abby Kinchy (2012) presents an ethnography of local anti-GMO movements in Mexico and Canada, focusing in particular on the attitudes and approaches to scientific knowledge within them. Both in terms of research methods and general approach, these books represent what will most likely be a growing interest in studying the cultural aspects of social movements in their relations to science in the years to come.

Abstract

The anthropology of science, technology, and society (STS) has emerged alongside a number of closely neighboring fields of scholarship. Four features distinguish the anthropology of STS: (1) a detailed interest in the sciences and technologies themselves; (2) a global perspective, not just an account from Western Europe and North America; (3) multilocale or multisited ethnographic access to complex distributed processes such as the global chemical industry or global clinical trials; and (4) a concern with the powerful aesthetics of imaginaries. The task of translating legacy knowledges into public futures draws upon four kinds of genealogies: test drives and libidinal drives, protocols and networks, landscapes or ethical plateaus, and reknitting global moieties split by the cold war.

Mapping the Field with Nearest Neighbors

The anthropology of science, technology, and society (STS) is in dialogue with real-world socio-political and cultural epistemic contests over ecological change, environmental damage, revenue seeking, sovereignty, and sustainability versus political–economic transformation, as well as with the creation of new science cities and globally distributed, locally modulated communities of scientists, engineers, and media developers.

The anthropology of STS emerged in the 1970s and 1980s, with work on physicists in the United States and Japan (Traweek, 1988), epistemologies of engineers, users, and communities of practice (Suchman, 1987; Cefkin, 2009), moral approaches to evolving medical testing (Fox and Swazey, 1974, 1992; Rapp, 1999; Martin, 1987, 1994, 2007; Clarke, 1998; Fujimura, 1996; Hogle, 1999), regulatory science and the law (Jasanoff, 1990, 1995, 2005), globally distributed industrial processes with unintended negative consequences (Reich, 1991; Fortun, 2001), and a 'cyborg anthropology' of prosthetic and experimental interfaces between silicon and flesh (Haraway, 1991, 1997, 2003; Downey and Dumit, 1997; Downey et al., 1995; Davis-Floyd and Dumit, 1998).

The anthropology of STS has emerged alongside, and broadened the purview of, a range of neighboring fields populated by sociologists, historians, philosophers, and bioethicists: (1) social studies of knowledge addressed itself to idealist accounts of scientific method, noting that tacit knowledge (Polanyi, 1974) and 'good hands' or skills in experiments are not easily transferrable through written protocols until stabilized in mature, repeatable, robust technologies (Collins, 1974; see also Fleck, 1935, on the troubles of stabilizing the Wasserman test for syphilis). (2) Actor–network theory (ANT) (e.g., Latour, 1988; McNeil, 1976; Mitchell, 2002; Spinage, 2012; Mahvunga, 2013) emphasizes that networks have obligatory points of passage that can reverse power ratios (e.g., from farmers' empirical knowledge to laboratory bacteriological science) and depend upon 'immutable mobiles' (the transfer of abstracted information distanced from locally modulated contexts). ANT promotes the methodological principle of including nonhuman 'actors' or actants within network analyses. (3) Social histories of science and technology (e.g., Galison, 1997; Fortun, 1993, 2008; Biagioli, 1993, 2006) have provided important coproducers of the anthropology of science and technology. (4) The social construction of technology approach (e.g., Bijker, 2002; Bijker et al., 1987) recognizes that technologies are not devoid of politics, that they are shaped by social histories, and that they can create new infrastructures for inequality.

What distinguish the anthropology of STS are four features:

1. A commitment to opening the 'black box' of the sciences and technologies, that is, to exploring their internal sociabilities, competitions, presuppositions, and articulations with managerial and political economy pressures. This involves unpacking enough ethnographically to be able to distinguish between aspirations and pragmatic pipelines of experimentation, and between what is a breakthrough and what is just normal science. It involves understanding the 'peopling' of the sciences and technologies: the importance of interpersonal relations and trust across disciplines, across institutions, and across national competitions on which the building and maintaining of these pipelines and platforms either work or do not. Opening the black box of science and technology is crucial to the anthropology of science and technology. It raises the bar of precision and refocuses what we think we know about how the world works in terms of both civic and technological epistemologies.
2. A global perspective that does not limit itself to Western Europe and the United States, thus continuing anthropology's longstanding charge of being a comparative social anthropology of the world and not just of privileged presumptive leaders or holders of political advantage. Here the rise of journals based in Asia (e.g., *EASTS: East Asian Science Technology and Society* and *Science, Technology and Society*) as well as the National University of Singapore's Biopoleis Project are harbingers of a more polycentric approach to global developments, many of which are happening in Asia.
3. A set of methods that can deal ethnographically (at the required close-up scale) with globally distributed technoscientific, political–economic, and socio-cultural

processes (at the required overview mapping scales). Doing ethnography at 'multilocale' or 'multisited' strategic points of access to multiscaled and distributed processes such as the global chemical industry, the global biotechnology industry, or climate change is an invaluable way of ground truthing, reality testing, and challenging models that use only aggregate data, superficial survey instruments, or results limited to laboratories divorced from shop floors, tinkerers, hackers, makers, and other users.

4. An artistic and literary aesthetics not only for writing the cultures of the sciences and technologies, but also for the imaginaries that inform new experimental discoveries, validating tests, as well as psychic and financial investments in new socio-technical infrastructures, conventions, and trade shows. Such liminal technoscientific spaces have long been terrains, for instance, for NASA exploration of extreme environments, cyborg possibilities, and space medicine. Among such artistic aesthetics that are increasingly pervasive are bioarts for democratizing scientific knowledges and making more visible and enjoyable the various sorts of care that maintaining living organisms require and the limits that such care and such knowledge of habitat interactions impose, while at the same time allowing the limits of possibility to be expanded.

A broader venue can be seen through the topics of recent anthropology of science and technology books and dissertations that include (nonexhaustively) the following: evidence law and the incorporation or exclusion of visual media from handwriting and finger printing to positron emission tomography scans and video animation, and the related topic of e-documents in a culture of cryptography; interpretive debates over the meaning of visualizing, amplifying, or proliferation technologies such as medical scans, tissue culture technologies, and clinical diagnoses; open software as socio-political as well as technical infrastructure, e-governance in Latin America, and e-kiosks in India; rationalized office design, e-tools for collaborative work at a distance, and its failures; Taiwanese biostatisticians as providers of bridging tools for global clinical trials, in a case of a nonrecognized country using expertise to be a player; biological citizenship after disaster, bioethnic conscription in disease studies, and bioavailability as biopolitics; surgical training, pharmaceutical marketing, and objective self-fashioning through drugs, and the turning of selves into clinical subjects; forms of biocapitalism under different national agendas; organ transplantation, its psychoses for patients, identity contradictions for physicians (in Turkey), moral rejection of organ transplantation (in Egypt), and transmission of structural biology through bodily performance; race and the marketing of medicine, genomics, and diversity; product design and safety law; executive coaching; psychiatry, depression, and negotiating different class and religion-linked public health discourses in Iran; epidemic and transgenerational addiction as a techno-culture of affect; computational a-life and American folk kinship idioms, deep-water marine biology and the logics of ancestry, and the microbiopolitics of bacteria and cheese; climate change vernaculars in Canadian First Nations, US evangelicals, corporate green audits, climate scientists in the public sphere, and climate science under different national agendas; biological crafts from do-it-yourself biologies and geometric modeling with yarns and plastics to molecular gastronomy and synthetic biology; citizen epidemiology, gas fracking, and endocrine disruptors; 'smart' electricity market making by engineers and traders in contrast to economists, and digital map making in contests between First Nations, mining geologists, and forest ecologists.

Translating Legacy Knowledges into Public Futures

Four genealogical cables, each made up of many wires or threads, feed into the anthropology of science and technology's translation of legacy knowledges into public futures, buffering future shock, and tracking emergent forms of life. I will call these four cables 'test drives and libidinal drives,' 'protocols and networks,' 'landscapes or ethical plateaus,' and 'reknitting global moieties split by the cold war.'

1. Test drives and libidinal drives: You beta test a new technology, you test a hunch or hypothesis, you test constitutional issues in court, and you have libidinal drives. Biology, arguably, has replaced physics as the lead in upsetting traditional understandings of how the world works. In biomedicine, we are arguably undergoing epistemic revolutions, all too slow for the desperately ill but stunningly fast in terms of the pedagogies in which we have been trained. Two indices for these epistemic changes – the molecular biology revolution and bioecological imaginaries – may be sufficient to direct attention and to indicate the cascades, ramifications, and implications of paradigmatic shifts. There are glimmerings not only that we might be able to biologically repair our organs, but also that the self–other distinction is far more complicated once we recognize that our bodies are composed of more microorganisms and metabolic processes than human cells. Not only might genomics help stop or mitigate pandemics such as SARS or avian flu, but also comparative genomics might help identify lively processes of defense and repair across species, a new bioecological imaginary. 'Test drives' is a name for the nexus of genealogies of getting to contemporary understandings, say, from the old idea of vitalism (i.e., that life could not be reduced to the laws of chemistry and physics) to the more contemporary recognition that indeed one can synthesize living tissue. Creating life from chemicals (again) in the lab is one meaning often given to the term 'synthetic biology,' but another is something already happening: the engineering of bacteria to produce fuel, detect arsenic in drinking water, or produce medicinal drugs. Test drives also evoke libidinal drives, the entangled emotional fears (dystopian implications) and desires (utopian ones) emplotted in popular genres and metaphors of speaking and writing about science and technology, such as the impossibilities of complete control in treating epidemics; the gaps between triumphalist development schemes and their down-geared implementations; and emotional investments in promissory venture capital and their socialities of discipline, coding, and incentivizing.
2. Protocols and networks: The genealogical thinking here involves the great debates over rationality and rationalities,

over pragmatism's understanding of the public sphere as called into existence through the unintended consequences of decisions made by experts, politicians, and others; open and closed societies; the autonomy of science versus directed science for social ends; the coproduction of political and scientific authority of science and through regulation; engineering models of social action of human and nonhuman actor–actant networks, cyborg anthropologies, parasites and viruses, companion species, and other biological fellow travelers; and open and closed cybernetic systems that can tend toward equilibria, spin out of control into disequilibria or positive feedback, or expand fractally, or autopoeitically, via self-correcting or self-destroying modes of self-assembly. I call these 'protocols' or 'writing in programmed object-oriented languages,' through which 'ontology' becomes mutated from philosophy's metaphysical (untestable) and singular 'ground of being' into malleable, plural, and utilitarian units (ontologies in the plural) that software engineers encode. The accent here is on experimentation, and on the productive disagreement or continuous dialectic between science and engineering.

3. Landscapes or ethical plateaus: Ethnography is not merely descriptive. Once heard or read, the travails of patients and doctors in Botswana's only cancer ward (Livingston, 2012) will be hard to forget. Such is the force of many ethnographic case studies: descriptive, ethnographic, comparative, and acknowledging global network perfusion throughout local worlds. Ethnography, moreover, as Livingston argues, can be an early warning system of problems that are just emerging (e.g., a cancer epidemic following efforts to control HIV/AIDS). The genealogical thinking here is ethnographic: finding out what scientists and engineers actually do, not what they say they do; following their production of social organizations, power plays, public demonstrations, infrastructures, and resources for the future; and following them through the multiple sites and scales of interaction with other disciplines, institutions, economies, polities, publics, and generations. While some social historians and autobiographies or memoirs of scientists have provided precursors, the anthropology of science and technology is relatively young, beginning in the 1970s and 1980s and picking up speed and range of topics in the 1990s. The accent here is on how scientists and engineers pursue their crafts; how those crafts have changed with new instruments, new communities of practice, and new research programs or national projects; and, in a larger sense, how general epistemes and knowledge ecologies have changed (e.g., how large data sets, computational strategies, molecular or nano-scale experimentation, and so on have changed how we think, perceive, and evaluate). Physics, biology, bacteriology and medicine, computer science and new media infrastructures, and ecological and environmental issues have all been brought under the ethnographic gaze, often with more than merely descriptive effects.
4. Reknitting global moieties split by the cold war: The calls of the twenty-first century are routed through switches, transducers, translations, and satellites from Mumbai and Shanghai, Bandung and Tehran, Chongqing and Bangalore, Dubai and Singapore, and elsewhere. Do these portals open into new epistemes, armatures, mythologies, and experimental regimes? The genealogical thinking here involves the rapid globalization of scientific and engineering competitions, such that STS or history and philosophy of science departments focused only on the United States and Europe (as has long been the case) are simply archaic and out of touch. The largest genomic-sequencing center in the world in 2013 is in China, over one-third of the postdocs in US biology labs are Chinese nationals, and a large number of Silicon Valley information technology entrepreneurs are part of the Indian diaspora, many of whom are returning to invest in a newly booming Indian and transnational economy. Acquisitions and mergers by once third and second world companies of first world enterprises are changing even the landscape of multinationals. Similarly archaic and out of touch are histories of science in India, China, or the Arab world that are simply nostalgic romanticizations of long-past glories, usually ending in the early modern period. Suddenly, the world is as if two moieties, or two halves, of a whole were allowed back into intimate exchange and interaction. The accent here is on competitive cooperation, translation, and getting along with partial understandings that have always been features of scientific and technological worlds, but that now take on increased salience, breadth, and bite across national boundaries of distrust and intense advantage seeking. The leading edges in this competitive cooperation are biosecurity and pandemic control; food, water, energy, minerals, and rare earths resource security; media, information, data, and tourist circuits; and trade and intellectual property regimes. Important harmonics in this competitive cooperation are also in the areas of holistic medicine to repair the limitations of biomedicine, experimental green city expertise, logistics and finance that are sustainable and less subject to unexpected boom-and-bust cycles, and conflict resolution over the long term involving new international and global regulatory regimes. All of these have become new areas of ethnographic-anthropological work, transforming the ways in which medical anthropology, economic anthropology, political anthropology, and studies of 'material culture' and technologies have previously been framed and conducted.

Open Futures

It is hard to keep the generations straight. Legacies channel and constrain futures, only later to be rediscovered or reconceived in new contexts, generating new and sometimes different directions of thought and action. Switching points among multifocal and multinational agendas and capacities, 'Gestalt' or 'paradigm' switches in new technoscientific ways of living; new ethical plateaus in arbitrating decision making across intersecting knowledges and imperatives; and coping with alterities, cyborgs and companion species, and rhizomes and parasites – these are some of the philosophical, semiotic, mechanical, and biological indexical terms of reference. They also gesture to knots or quiltings, striations and inequalities, of emergent forms of life. Li Shizhen (1518–93) and Garcia da Orta (1500–68), who were at different ends of the Silk Road (Yangtze and Goa, respectively) and were collectors of

materia medica, founders of botanical gardens, and compilers of the medical empirical knowledges of their times, are parts of the varied moieties pulled apart by historical polities that now are reknitting into new fabrics of exchange and competition.

Abstract

Computers and information technology have over the past 50 years moved from being a social and engineering form which 'impacted' society to being core to our social fabric – much as we cannot study an ecosystem without considering water supply, so we cannot study any part of society without considering the flow of bits and bytes. The richly textured fabric of this fundamental social change has been studied at various levels, without there being as yet a single integrating vision. This article identifies some key levels and points to possibilities for an integrated understanding.

Introduction

Taking 1992 as the date of origin for the World Wide Web, then every child and adolescent, every young adult, has grown up in a world as the web's meshes were becoming ever finer. Access is not easy or universal, and there have been continuing stalwart efforts on the parts of industry and governments to ensure that this remains the case across the developing and developed worlds. It is not that everyone is on the web; rather that the businesses of business, government, war craft, education, and entertainment have become increasingly dependent on web use – so the nonuser is still caught in this inexorable flow. You simply cannot do a sociology of the social without addressing the pervasiveness of computing. Therfeore, I could fight my designated title and assert that really all contemporary sociology is implicated in the social study of computers and information technology.

However tempting the *mise en abyme* of this whole encyclopedia might be, I will follow a more modest path. In a computer-free context, Jacques Revel once wrote: "the change in the scale of observation revealed not just familiar objects in miniature but different configurations of the social" (Revel, 1995; cited in Feierman, 1999, p. 206). I take his tack to analyzing social studies of computers and information technology; in so doing, I explore social and political work done at the various layers of computing and information technology before finishing with some integrative visions.

From the early nineteenth century on, we have seen the growth of vast amounts of data collection about our citizens – the rise of national censuses leading to a flourishing of the arts of statistics (etymologically information about the state) and classification. Information and communication technologies such as the steamship, the railway, and the telegraph vastly increased the number of connections to be made socially, and the extent and potential sway of empires pulsing with a single beat. A large, interconnected population must be able to be managed; the great national censuses provided the key move of taking us from dealing with people in contexts to dealing with classes of people and reasoning our policies on the basis of these classes. In the same way, the great natural history surveys over the same period allowed us to conceive of nature as something to be managed, within human temporality, rather than an infinite resource to be exploited. Information infrastructures accompanied these developments – whether with the origin of computing in the organization of the massive insurance agencies that blossomed in the nineteenth century (and whose actuarial tables, later to serve as a basis for epidemiology, relied on census techniques) or the origin of computing in the development of the Hollerith punch-card machine, which enabled the processing of vast datasets in the 1890 American census (Yates, 1989; Campbell-Kelly, 1989). In the mid- to late-nineteenth centuries, railway and insurance industries were the two great behemoths of private enterprise. The railway industry was crucial, as Chandler (1977) notes, for the development of new forms of organizational management, as was the insurance industry. The big thing here was the problem of how to sell insurance to those who traditionally could not afford and would not consume it (in the words of a modern entrepreneur, they were competing with nonconsumption). To make it affordable, you needed really precise actuarial tables (of which more anon) and very low-cost procedures for both gathering those tables and processing claims – the margins were very thin, so every efficiency counted. Thus, as Martin Campbell-Kelly (1989) argues, new forms of office organization were developed around the drive for flows of data/information. Punch-card technologies, such as the Hollerith machines, were developed in the context of this preprepared niche. In a sense, the niche created the technology which in turn developed the niche in wildly new directions – a form of circular causal chain that is familiar to biogeographers (it is interminably circular to ask whether the niche or the terraforming organism came first). (Ian Hacking (1998) in his work on the traveler's fugue makes a similar argument about niches and railway technology in mental disorders.) Hence, fairly directly, office organization gave us a second computer precursor.

And then came the Second World War. In a stunning investment in an untried concept, the US government plowed the then enormous amount of $US 3 billion into a massively

[†]Deceased.

interdisciplinary project involving chemists, mathematicians, physicists, and engineers in order to create a singular weapon of mass destruction – the atomic bomb. A major issue that developed along the way was that you needed very complicated, dense, and precise mathematical calculations in order to get conventional explosives to create just the right symmetric implosive force to bring the core of the weapon to critical mass and unleash the furies. One of the first electronic stored-program computers, the ENIAC, was born. Hence, fairly directly, a scientific need gave us a third computer processor. (There are two other stories one could tell here – about Norbert Wiener, cybernetics, and antiaircraft guns; or about Alan Turing and code-breaking – which would complicate the picture in interesting ways.)

The lesson to be drawn from this is that if one looks at 'computers' and 'society' as separate and separable things, then one immediately gets drawn into some kind of determinism. With the fundamental cognitive tools of our time, we are dealing simultaneously with industry, organization, and science – and while we might not have a good word for that which is developing and subtends all three, we need the concept if we are to make sense of the question of digital technology, sociality, and epistemology. Further, we need to understand that occurrences of new digital epistemology (and ontology) can be traced back to earlier branches of the Tree of Knowledge – they certainly predate the Apple.

Automation and the Impact of Computerization

Many early studies of computers and society or computers and organizations concerned computing as an automation of human work. These included two major analytical concerns: the replacement of humans by machines in the workplace and the 'deskilling' of existing functional jobs (Braverman, 1998). Later, the analytic picture became much richer, as researchers realized that automation and deskilling were just two dimensions of the picture. An early breakthrough article by two social-computer scientists defined this territory as 'the web of computing' (Kling and Scacchi, 1982), a term that became a touchstone for the next generation. It refers to the co-construction of human work and machine work, in the context of complex organizations and their politics. Much of this research took place in business schools; some in departments of sociology or industrial psychology. In Scandinavia and other regions with strong labor unions, partnerships between the unions and researchers were important, at first focused on job replacement and deskilling, and later on computer systems design created through partnerships with users, social scientists, and computer designers.

The social impact of computing remains a strong research strand worldwide, despite the anthropological fact that finding 'untouched tribes' is increasingly difficult. Thus, the problematics of interest to science and technology studies (STS) have shifted from understanding the initial impact on a group or institution, to understanding ongoing dynamics such as usage, local tailoring of systems, shifts in design approaches, understanding the role of infrastructure in helping to shape impacts, and the ecology of computers, paper, telephones, fax machines, social media, face-to-face communication, and so forth – dynamics that are commonly found in most offices, and increasingly in homes and schools.

The Emulation of Human Cognition and Action (Artificial Intelligence and Robotics)

The early program of artificial intelligence (AI) work, beginning in an organized way during World War II, was to create a machine that would emulate human thinking (classic AI) and action (robotics). Some of the emulation work came in the form of intelligent tutoring systems and expert systems (Wenger, 1987) meant to replace or supplement human decision-making. The decision-making side of the research continues to be strong in management schools and in government agencies; it is often critiqued by STS researchers, although some do use these tools (Gilbert and Heath, 1985; Byrd et al., 1992). The discussion about whether emulation of human thinking would be possible dates far back; it came to the attention of many STS researchers with the work of philosopher Hubert Dreyfus (1979, 1992), who argued for the irreducibility of human thought, perception, and action to computerized mechanisms. Later STS researchers (including Diana Forsythe, Susan Leigh Star, and Lucy Suchman) formed direct collaborations with AI researchers. These partnerships took both critical and system-building forms; in both cases, the social science researchers acted as informants about the nature of the 'real world' as opposed to that of the emulated world of AI. AI changed during the late 1980s and early 1990s – some computer scientists spoke of the 'AI winter,' referring to funding problems unknown in the 1970–88 period. As personal computing and e-mail spread, and later, the Web (1992→), and the early promises of AI seemed not to be paying off, AI began to lose its prestige within computer science. Many AI researchers changed to problems in information science, software engineering, or cognitive science. Researchers in a branch of AI, distributed AI, continued to interact with the STS community (Huhns, 1987; Star, 1988). Their interests were in modeling and supporting spatially and temporally distributed work and decision practices, often in applied settings. This reflected and bridged to STS concerns with community problem-solving, communication and translation issues, and the division of labor in large scientific projects.

The Enterprise of Computing, Its Military Roots and the Role of Activism

In 1983 US President Ronald Reagan introduced his (in) famous 'Star Wars' (officially known as the Strategic Defense Initiative or SDI) military defense program, a massively expensive attempt to create a distributed laser and missile-based system in space that would protect the USA from foreign attack. The proposal put computer scientists, and especially software engineers, at the center of the design effort.

An immediate outcry was raised by the computing community as well as by alarmed STS scholars close to it. There were concerns that a system of that magnitude was untestable; tools were lacking even to emulate the testing. There were concerns about its technical feasibility. There also were concerns about

its ecological impact on the field of computer science – concerns akin to those raised by organismal biologists about the Human Genome Project – that the lion's share of research funds would be funneled into this project, orphaning others.

A new group, Computer Scientists for Social Responsibility (CPSR – http://cpsr.org), was formed in Silicon Valley as a focus for these concerns. The group quickly found common ground in many areas, including activist, ethical, policy, and intellectual questions. It has flourished and now sponsors or cosponsors three conferences a year in which STS scholars often participate: Computers, Freedom and Privacy (policy); Directions in Advanced Computing (DIAC) (intellectual and design directions, and their political and ethical bases and outcomes); and the Participatory Design Conference (PDC) (which brings together users, community organizers, computer and social scientists who work on issues of codesign and appropriate technology) (Kyng and Mathiassen, 1997). CPSR, as with its counterparts in the UK (Computers and Social Responsibility) and elsewhere, became an important meeting ground between STS and computer/information science. This was especially true of those critical of military sponsorship of computing agendas (at one point in the US some 98% of all funding of computer science came from the military, especially ARPA – the Advanced Research Projects of the Army (formerly DARPA), arguably the critical actor in the creation of the Internet (Abbate, 1999).

Beginning in the 1980s, a grassroots movement sometimes called 'community computing' arose, and linked with CPSR and other similar organizations. It attempted to increase access to computing for poor people and others disenfranchised from computing for a variety of reasons (Bishop, 2000). This often involved the establishment of 'freenets,' or publicly available free computing. Terminals were placed in venues such as public libraries, churches, and after-school clubs; some were distributed directly to people in need. This general problematic came to be called the 'digital divide,' and formed an active nexus of research across many areas of interest to STS.

An important part of the attempt to enfranchise everyone arose in the world of feminist activism and scholarship, as early computer hackers were nearly all male, and there were sexist and structural barriers to women as both users and professionals. Another meeting place between STS and computer/information science was formed by numerous conferences on women in computer science, gender and computing, and feminist analyses of the problem choice and ethics of computer science. An excellent series of conferences, whose proceedings are published in book form every 4 years, is sponsored by IFIPS (the International Federation of Information Processing Societies, Working Group 9.1, entitled Women, Work and Computing). See, for example, Grundy et al. (1997).

The 'Scandinavian School'

In the 1950s the (powerful) trade unions across Scandinavia helped to pass the 'co-determination legislation.' These laws stated that unions must be involved in technological design – originally motivated by concerns about deskilling and job loss through automation. A form of sociotechnical systems analysis evolved into a set of techniques for studying work places and processes. As computers arrived in the workplace, this came to include progressive computer scientists and social scientists, many of whom now participate in STS publishing and conferences, as well as Computer Supported Cooperative Work, Human Computer Interaction, and Participatory Design conferences (Greenbaum and Kyng, 1991; Bjerknes et al., 1987; Bødker, 1991; Neumann and Star, 1996). Gregory (2003) discusses the democratic bases of the multilevel Scandinavian participatory design approach – in particular their comfort with working through conflict and contradiction.

Computing, Standards, and Design

Although we rarely look under the hoods of our own computers, their formal structure and the protocols that allow them to interoperate are core sites of social and political activity. As Laura DeNardis (2009) so beautifully demonstrates, the whole issue of Internet governance is played out in standards-setting bodies who make decisions with vast sway. While standards in general remain somewhat understudied, they are the key to understanding the imbrication of social policy, computing, and design.

This theme has been explored beautifully by Steven Jackson (2014) in an article on the 'design policy knot.' They argue that when dealing with issues such as privacy and trust (core to our computing environment), we cannot look at design as an activity precursor to or separate from policy deliberations: our policies become part of the very information infrastructures we create (Braman, 2007). This lock-in occurs at the deepest level – as Helen Nissenbaum and colleagues have uncovered while exploring the Future of Internet Architecture projects funded by the National Science Foundation. It is possible, for example, to 'hardwire' the Internet for digital rights management; it is a political issue whether to do so.

Nissenbaum developed with Geoffrey C. Bowker, Susan Leigh Star, and Carl di Salvo, among others, the Values in Design movement, which through extended workshops held in the United States and Europe has trained graduate students in the methods of social studies of science and in design principles so that they can recognize and inflect the values that get built into all information systems. The databases that we use to store our information are a case in point. Attempts to fit 'indigenous knowledge' (the term is multiply problematic) into our own database structures is a perspicuous site for these issues. As Cori Hayden (2003) has shown, one method used by big Pharma has been to slot this knowledge (which they are mandated to collect) into unstructured text fields – making it extremely difficult to access, since databases take on their power through operations performed over multiple fields. The Indian Traditional Knowledge Digital Library makes the knowledge searchable, but at the price that it can only really be used to protect intellectual property claims – a mission itself alien to the knowledge producers themselves (Rajan, 2011). Helen Verran, Michael Christie, David Turnbull, and Ramesh Srinivasan have worked with aboriginal and Native American groups to represent their knowledge in its own terms – a drive that fits into the broad rubric of 'postcolonial computing' (Philip et al., 2012).

Knowledge Infrastructures

Recent decades have seen the rise and dissolution of categories such as 'digital libraries,' or 'scientific cyber-infrastructure' (when we were in a transition from laboratory-based to computer-based scientific work). We have now entered the age of the computer-based retronym where these qualifiers have become unnecessary. However, there has been a body of pioneering work within the field of STS which has tracked and theorized this transition.

Star and Ruhleder (1996) wrote a classic paper trying to untangle just what an (information) infrastructure was. Their categories – embedded in **Figure 1** – were notably not centered on the technological base alone, but on a set of sociotechnical observations. These have proven fertile in providing a definition that led to research developments of a range of concepts on old and new themes, such as invisible work, legitimate peripheral participation, and ontic occlusion (Cory Knobel). Millerand, Baker, and Bowker subsequently developed the Cartesian grid in **Figure 1** as a means to explore design decisions taken as cyber-infrastructures are built – the argument here being that willy-nilly designers chose to situate their decisions along local/global and social/technical axes. This concern with design reflected the changing role of researchers in this field. Where early science studies practitioners argued that the social scientist should not directly participate in the field they were studying, those studying the establishment of distributed, computer-mediated patterns of work increasingly found themselves drawn into working with developers (Ribes and Baker, 2007). This move represented an integration of science studies and information science (as practiced by the iSchools, themselves inheritors of the tradition of Library and Information Science). An influential report on Understanding Infrastructure has since been widely used in the policy and scientific literature – this has been complemented by a report on Knowledge Infrastructures, where the focus is centrally on the configurations of humans and nonhumans needed (see web references below).

In order to understand an emergent information infrastructure, one needs to be able to understand codes and conventions as well as observe practice. Paul Edwards (2010) demonstrated this brilliantly with respect to climate change – showing, for example, that modeling assumptions often got built into code and passed on through generations of programs without the scientists concerned being aware of the transmission. Lev Manovich has laid the framework for the emergent field of software studies, which is developing techniques for the critical analysis of computer code.

Mobile Technology

The most significant trend in computing over the past 20 years has been the rise of mobile devices. In the field's early days, a computer was a large machine in a cold room plugged into a wall – today most people would have difficulty enumerating all the computing devices distributed throughout their homes and about their persons. They have moved into being part of the very fabric of social life. The field of Ubicomp (ubiquitous computing) has grown up to track this and design for it.

A core question here has been whether what it means to be human and to be social is changing. There is a line of argument that we are just doing the old things in new ways. Thus, in a classic paper entitled 'A Rape in Cyberspace,' Julian Dibbell (1993) demonstrated that an online libertarian community soon grew rules very similar to those operating in 'normal' society when encountering deviant behavior. The myth of the early Internet was that it was open to all, free and democratic – today a handful of media companies holds vast sway over our collective attention economy and governments and

Figure 1 Cyber-infrastructure as *distributions* along technical/social and global/local axes.

corporations are attempting to build what are called 'walled gardens' – isolating the innocent user from tempestuous anarchy. The other end of this equation is the questionable assertion that new social and political movements have been enabled by mobile technology – the misnamed Arab Spring and the Occupy movement for example.

While this business-as-usual case can be somewhat persuasive, it does fall down when one recognizes that the very stuff of sociality is changing. A good analogy here is with the development of long-distance telephone networks in the last century. In the 1980s, there were myriad advertisements trumpeting the virtues of the telephone for keeping families together; yet they also helped drive families apart by allowing constant contact at a distance. Being a family member for many in the developed world came to involve trains, planes, automobiles, and telephones. Today it also involves Facebook and Twitter and their like. This interposition of (expensive) technology between people exercising social and political functions is business as normal for us – it does, although, speak to the need for radically rethinking our categories. Perhaps the most interesting theoretical development here has been Dominique Boullier's (2011) work on 'habitele' – or living at a distance. He is exploring how all aspects of our lives (reading, watching films, keeping calendars, transferring money, and so on) are converging onto our mobile devices, to the point where it is a misnomer to call them phones.

Big Data

Along the way, we are gathering huge amounts of data about ourselves and each other. Part of this is the traditional dream of social engineering – most immediately inherited from cybernetics: the controversy in 2014 around Facebook carrying out social experiments on their unwitting users is a case in point.

There are three dimensions of interest here. First is the development of new analytic tools by social scientists to study their objects. Thus, there have been a number of attempts to produce 'distant readings' (Moretti, 2013) of large text corpera and to do 'trace ethnography' (Geiger and Ribes, 2011). Distant reading is a technique akin to (but developed independently of) coword analysis – one seeks to identify patterns within huge text databases, such as the Ecco database of all published English language eighteenth century texts (de Bolla, 2014). Second is use of big data for surveillance and control by governments and corporations. This work draws in part on Foucault's concept of governmentality – what does it take to be able to govern one's citizens? Third is the study of ways in which we are wearing personal technologies which monitor our activities and provide us constant feedback. This Quantified Self social movement is currently being extended to monitoring bracelets, shoes, cars, and clothes.

Integrative Visions

The field of social studies of science had one origin in epistemological (David Bloor) and ontological questions (T.S. Kuhn) that constituted a discourse among historians, philosophers, and social scientists. The ontological status of 'nonhumans' has been a core question for Actor Network Theory (ANT). It is arguable that this interest itself derives in part from the history of computing – notably the field of cybernetics by way of Michel Serres. However one comes down on that issue, it is notable that technical talk today of the Internet of Things is wading in these ontological waters (Bogost, 2013).

The most interesting front in today's research is exploring our new social ontology. Dourish and Mazmanian (2013) are developing a corrective to the 'mind/body' split in much analysis of computing – bits and bytes do not exist in a 'cloud' but typically in vast distributed server farms; they have weight. The question of what it means to be human is changing fundamentally, and our field is primed to track this change. Jed Brubaker (Brubaker et al., 2013), for example, is exploring the changing nature of death by looking at death on Facebook – his findings range from the status of a dead person's account (Is it part of their identity, can it be 'passed on'?) to a body of users convinced that the heavenly host track their own Facebook accounts. The nature of memory is changing – just as our cognition is distributed among people and tools, so is our 'memory' increasingly not stored in the head or located elsewhere (a reference library).

A fundamental change in means of holding, storing, and sharing information is a rare historical event – one thinks of the origin of writing and the technology of the list; the invention of the printing press, and the technologies of absolutist bureaucracy together with the legacy of humanism (Clanchy, 1993). It constitutes a Kuhnian paradigm shift in the sense that fundamental social and political concepts no longer mean what they used to under previous regimes – indeed, it makes no sense to seek a continuity in the terms over the chasm. For a government to be 'democratic' means something different before and after the invention of a national press. This is being most closely felt today in the institutions of 'privacy' – the latter is just not a useful term in the modern state. For a person to be a member of a social group means something different with the invention of mobile technology. The so-called natural world is a different thing when you have terabytes of data from streaming sensors used in its monitoring and control. We as a field are realizing a return to our origins through increasing recognition that sociology, history, and philosophy can only advance hand in hand as we begin to understand the epochal transformations we are witnessing.

Acknowledgment

This article is based on work by Susan Leigh Star; updated by Geoffrey C. Bowker after her death. I have left Leigh's work, which describes the development of the field until 2000 largely untouched. I am indebted to Judith Gregory for her very helpful comments and changes – performed while on holiday and with broken toes.

Abstract

Ethnomethodology is a research program that studies the situated production and coordination of social practices. Starting in the 1960s, ethnomethodologists studied practices in a broad range of ordinary and professional settings. Ethnomethodology's orientation to local practices and situated knowledge influenced constructionist, actor-network, and discourse analytic approaches in science and technology studies (STS). Ethnomethodologists treat social science research practices as having no special epistemological status in relation to other scientific and nonscientific practices they study. This research policy is known as ethnomethodological indifference, and it is similar in some respects to the symmetry postulate in the sociology of scientific knowledge. However, unlike many STS scholars, ethnomethodologists do not treat professional sociology as a basis for authoritative explanations of other practices. Ethnomethodology has been criticized for its apparent lack of epistemological foundation and normative commitment, but proponents of the approach argue that their understandings and judgments have an ordinary basis in communal life rather than an epistemological foundation furnished by an academic school, theory, or method.

Ethnomethodology is a sociological approach to the study of practical actions, which has influenced the development of constructionist, actor-network, and discourse analytic approaches in science and technology studies (STS). This influence is explicitly acknowledged as an important part of the 'practice turn' in philosophy, history, and social study of science (Schatzki et al., 2001; Soler et al., 2014). Ethnomethodology's legacy also remains implicit in the now-commonplace talk of local practices, situated knowledge, discourse, and reflexivity in studies of science, technology, and medicine. In addition to the having pervasive influence throughout STS, ethnomethodology continues to develop distinctive lines of research on scientific and technical practices.

In the 1960s, Harold Garfinkel (1917–2011) coined the term *ethnomethodology* as a name for a unique sociological approach to practical actions and practical reasoning (Garfinkel, 1967, 1974; Lynch, 1993: 3–10; vom Lehn, 2013: Chapter 5). Early in his career, Garfinkel developed an interest in sociological theories of action (especially that of Talcott Parsons, 1937), but was dissatisfied with the way such theories glossed over the practical reasoning and interactional exchanges that characterize ordinary situations of action. He found inspiration in existential phenomenology, and particularly Edmund Husserl's and Alfred Schutz's phenomenological conceptions of the lifeworld. Others, and to some extent Garfinkel himself, also draw upon Ludwig Wittgenstein's later philosophy with its emphasis on language as practical action (Coulter, 1989). Literally defined, ethnomethodology is the investigation of 'folk methodology' for producing the innumerable practical and communicative actions that constitute recurrent social activities. However, the term 'methodology' should not be understood to suggest that 'folk' practices are designed along the lines of canonical scientific (or social scientific) methods. Instead, as ethnomethodological studies of routine scientific work have demonstrated, the practices in question – whether taking the form of family dinner table conversations or routine procedures in scientific laboratories – involve orders of discursive and embodied actions that rarely register in formal accounts of method.

Ethnomethodological Indifference, the Symmetry Postulate, and Reflexivity

Unlike methodologists in the philosophy of science who attribute special epistemic status to scientific methods, ethnomethodologists examine methods for composing and coordinating ordinary as well as scientific activities. Garfinkel used the term 'ethnomethodological indifference' to emphasize that any method whatsoever is worthy of study, regardless of its professional status, relative importance, adequacy, credibility, value, and necessity (Garfinkel, 2002: 170; Garfinkel and Sacks, 1970: 345–346). This does not mean that ethnomethodologists do not care about questions of value and validity; instead, it means that they believe that prior assumptions about the importance or validity of particular practices should not limit the choice of research topics. Not only might further investigation reveal that such preconceptions are misleading, but such investigation might also demonstrate that apparently trivial practices are organizationally important and resilient features of social life. And, in many cases, the investigator is in no position to make an ultimate judgment about the validity and value of the practices studied.

Ethnomethodological indifference is similar in some respects to the more familiar 'symmetry postulate' of the Strong Program in the sociology of scientific knowledge (Bloor, 1991[1976]: 4–5). The symmetry postulate is that the same general form of (social) explanation should apply to theories or doctrines of all kinds, regardless of their current standing as scientific or not, and regardless of whether the analyst initially holds them to be true, false, successful, or unsuccessful. However, there is a significant difference between ethnomethodology and the Strong Program, which is that the former delves into the practical and interactional production of embodied and discursive activity, while the latter focuses on more abstract contents of knowledge, and proposes to use established sociological concepts and methods to explain what passes for knowledge in a given time or place. Despite embracing a version of relativism, and contrary to accusations that his program is antiscientific, Bloor (1991[1976]: 160) explicitly embraces scientism for his program, not as a fallacious effort

to boost credibility but as an 'optimistic' orientation to the possibility of gaining objective (social) scientific knowledge. In part, the difference between Garfinkel's and Bloor's programs has to do with a less-obvious implication of the term ethnomethodology. In addition to being a name for an academic field that studies folk methods, the term refers to methodologies – systematic analyses of investigative procedures and evaluations of their efficacy – which are integral to many practices studied as well as the social scientific methods used for studying them. Many social scientists (including quite a few in STS) assert that scientists conduct their research unreflexively, unaware of the extent to which they implicitly construct the qualities they assign to nature, and that the intervention of an outside analyst is necessary for unmasking, explaining, and criticizing the tacit epistemologies and ontologies. In contrast, ethnomethodological indifference extends to the privileges ascribed to social scientific analysis itself:

> Persons doing ethnomethodological studies can 'care' no more or less about professional sociological reasoning than they can 'care' about the practices of legal reasoning, conversational reasoning, divinational reasoning, psychiatric reasoning, and the rest.
>
> Garfinkel and Sacks, 1970: 142

Not only does such indifference apply to topics of investigation, it also applies to methods. Perhaps most obviously in the natural sciences, systematic practical activities often include extensive methodological inquiry and debate. Natural science methodologies are often held up as exemplary, but scientists are not alone in the way they devote sustained attention to their own methodic practices. In modern (and also many ancient) societies, large bodies of literature, and countless conversations, instruct, articulate, discuss, and debate the practical, epistemic, and ethical character of a broad array of practices, including religious practices, legal procedures, etiquette, food cultivation and preparation, sexuality, child rearing, and many recreational activities. Any effort to explain such practices sociologically must first come to terms with the fact that explanations of many kinds (including social explanations) are reflexively embedded in the history, production, and teaching of the practices themselves.

Ethnomethodological Reflexivity

Garfinkel (1967: 1) spoke of the 'reflexive,' or 'incarnate,' character of accounting practices and accounts. By this he meant that social activities include endogenous practices for displaying, observing, recording, and certifying their own regular, normative, and rational properties. In other words, social agents do not just behave in orderly ways; they examine, record, and reflexively produce their actions. This particular sense of reflexivity emphasizes collective, and often highly organized, accounting practices, and differs from the Enlightenment ideal of critical self-reflection. Rather than reserving reflexivity for the savant, ethnomethodology begins with the observation that the persons and organized groups that social scientists study already observe, describe, and make sense of their own methodic practices, and that when confronted with social science findings that conflict with their own understandings, they are likely to remain unmoved (for different views on ethnomethodology's stance on reflexivity, compare Lynch (2000) and Pollner (2012)).

Bruno Latour, who occasionally expresses a qualified affiliation to Garfinkel's ideas (see Latour, 2005), also makes a deflationary move to locate reflexivity in a flat landscape in which the social or cultural analyst dwells alongside the practitioner, rather than viewing practices abstractly from an imagined height above that world. He argues that "journalists, poets and novelists are not naive make-believe constructionists. They are much more subtle, devious and clever than self-conscious methodologists. They did not have to wait for post-modern writing to tell stories; they are as self-conscious as those who naively believe they are *more* self-conscious" (Latour, 1988: 170).

Ethnomethodology's orientation to 'endogenous' or 'incarnate' accounting practices does not require an uncritical acceptance of official doctrines. For example, scientific reports and scientists' reminiscences sometimes describe scientific practices in ways reminiscent of Mertonian norms and empiricist ideals, but rather than accept such accounts at face value a historian or ethnographer needs to pay attention to the more pervasive way in which methodic understandings, and understandings of method, play a constitutive (and sometimes subversive) role in a science under study. For ethnomethodologists, the research question is not just "How do a society's (or scientific field's) members understand their social world?," but "How do members perform actions so as to make them accountable – that is, intelligible, recognizable, and acceptable in the relevant field of practice?" Accordingly, reflexive accounts are not limited to thoughtful ruminations about past actions and present circumstances; they are themselves prospective and retrospective actions performed in unfolding public interactional situations, and thus they help constitute the very contents of the fields of practice in which they occur.

Topic and Resource

The idea that explanations, explanatory concepts, and, more generally, natural language resources are common to professional sociology and the activities sociologists study, is a source of long-standing consternation and confusion in the social sciences (Winch, 1990[1958]; Hutchinson et al., 2008). As Garfinkel and Sacks (1970: 337) noted:

> The fact that natural language serves persons doing sociology, laymen or professionals, as circumstances, as topics, and as resources of their inquiries furnishes to the technology of their inquiries and to their practical sociological reasoning its circumstances, its topics, and its resources.

An injunction developed by ethnomethodologists (Zimmerman and Pollner, 1970), and adopted by proponents of discourse analysis (Gilbert and Mulkay, 1984) is that social analysts should not confuse topic and resource. That is, they should not confuse the common sense explanations given by participants in the social activities studied with the analytic resources for studying those same activities. A variant of this injunction in social studies of science warns the analyst not to adopt, for polemical purposes, the rhetoric of scientific authority that their own studies make problematic (Woolgar,

1981; Ashmore, 1989). However, if it also is the case, as Garfinkel and Sacks suggest in the above quotation that both topics and resources are furnished by the social world in which the analyst is embedded, then it remains unclear where the professional analyst can turn to find a standpoint that is not already occupied by the actor – an actor, as conversation analysis reminds us, engages in 'analysis' as a means of interactional production. This question is taken up in the following section.

Ethnomethodology and the Problem of Description

In recent decades, STS has undergone a 'normative turn' (Lynch, 2014), and many participants in the field no longer are satisfied (if they ever were) to pursue the descriptive, nonevaluative orientation that characterized both the sociology of scientific knowledge and ethnomethodology. However, if it is the case that pragmatic methodologies, analytical concepts, and discursive repertoires are reflexive to social settings, independently of any social science methods that would describe them, this certainly should be the case as well for ethical and moral evaluations. The normative turn thus continues to face the problem of how any analytical account (and certainly any evaluation or recommendation) stands with respect to those accounts that are already generated in the settings investigated. Social scientists who have cut their teeth by refuting analytical strategies that invoke the superior validity and perspicacity provided by a (social) scientific perspective – a perspective is presumptively more objective than the common sense myths, superstitions, and ideologies of the benighted natives – no longer can fall back upon such strategies. This is why the problem of description is so acute for social and cultural analysts who conspicuously eschew the epistemic privileges associated with the natural and social sciences.

Ethnomethodologists do not agree upon a single solution to the problem of description, and contradictory ways of handling it are evident in the field, but some ethnomethodologists dissolve the problem by arguing that sociological descriptions do not require special theoretical or analytical auspices in order to be intelligible and cogent. As Sharrock and Anderson (1991) argue, under most circumstances in which descriptions are made and accepted as adequate, there is no need (and, in any case, no prospect) to overcome epistemological skepticism by attaining an extraordinary degree of certainty. Consequently, the unavoidably reflexive relationship between epistemic contents and existential conditions is not a 'methodological horror' (Woolgar, 1988: 32) that makes description or explanation impossible or essentially problematic, because an ethnomethodologist is in no worse (or better) shape than anyone else who would write intelligible, cogent, and insightful descriptions of particular states of affairs. Even so, there still remains the question of the scientific, or other, grounds for ethnomethodological descriptions.

The Possibility of 'Scientific' Descriptions of Human Behavior

A possible basis for ethnomethodological descriptions is presented in an early argument written by Harvey Sacks (1992: 802–805), the founder of a field that later came to be called conversation analysis. This was a brief, but intriguing, argument about the possibility of developing a science that produces stable, reproducible, naturalistic accounts of human behavior. Sacks observed that natural scientists already produce accounts of human behavior when they write natural language descriptions of methods for reproducing observations and experiments. Social scientists who attempt to describe methods in a broad range of professional and nonprofessional activities are in no worse of a position than natural scientists who attempt to describe their own particular methods. In other words, Sacks conceived of the replication of experiments as a particular (but not necessarily special) case of the reproduction of social structures. While social scientists generally do not aim to produce manuals on how to perform the activities they describe, they can write accounts of social actions, which are adequate in a praxeological sense: adequate to the production and reproduction of the relevant practices.

Instructed Actions

It is well-established in the sociology of science that replication is problematic. Instead of being a methodological foundation for establishing natural facts, particular instances of experimental replication often beg further questions about the detailed conditions and competencies they involve (Collins, 1985). To say that replication is problematic does not imply that it is impossible, but it does raise the question of how scientists manage to secure assent to the adequacy of their experiments. The phenomenon of just how scientists conduct experiments, and how they establish particular results in the relevant communities, has become a major topic for social-historians and ethnographers of science. Consequently, in the more general case of the reproduction of social structure, it seems reasonable to conclude that Sacks identifies a phenomenon for further ethnomethodological investigation, but not a grounding for a possible sociological research program (Lynch and Bogen, 1994). Garfinkel (2002: Chapter 6) names this phenomenon 'instructed actions.' Such actions involve two parts: first, a formal (written, formulated, or otherwise transsituational) set of instructions, such as a recipe, a description of how to do a laboratory method, a procedure described in a manual, etc. and, second, a singular effort to follow or enact the instructed action. The pairing of the two is the phenomenon. That is, the question to be investigated in any case is how formal instructions relate to instructed actions. This relation might be said to involve a variant of the hermeneutic circle, but instructed action is not an interpretation of a text, it is instead a course of worldly action in particular environments in which textual resources are used in an improvised way. Variations on the theme of instructed actions are endless, depending on the occasion, the media in which the instructions are conveyed, the competency of the reader, and so on.
